| Unexpended Revenue | | \$5 856.90 |

APPENDIX NO 3

REPORT OF THE TREASURER

In presenting the treasurer's report for 1939, there are several conditions in common with those of the past three years. One is the recurring difficult problem of investing and reinvesting safely the available funds of the Society. Another condition is the low rates of interest now to be obtained on prime bonds. A third is the growing feeling that prices for such securities have reached their peak. All these conditions have influenced the Treasurer and urged a conservative policy of investing our funds, having in mind the possibility of serious inflation with a consequent fall in prices of long term bonds. Also, a result of the above has been to oblige him to carry a larger cash balance than usual. Our policy should be, therefore, to try to be reasonably sure of the principal, and at the same time, expect only a moderate income return.

Revenue, in 1939, from resident annual dues amounted to \$49,355 the largest amount ever received from this source. The Society is growing in numbers of fellows. Non resident dues, in 1939, amounted to \$1559, so that the total of annual dues was over \$50,900. Additional income, received from invested funds (\$3844 65), from sales of the *Directory* (\$16 16), and from profits from securities matured and sold (\$814 67), combined amounted to \$4675 48. Hence, the total revenue of the Society (not including that of the Building Fund) in 1939 was \$55,590. Again, this is the largest sum ever received in a year by the Society.

Regarding the Building Fund, the Treasurer, in accord with a vote of Council, February, 1939, marked down

two items (for years in default) a total of \$8135. In 1939 the Fund received income of \$1907, a generous gift of \$1000 from a loyal friend and a small profit of \$142.50 from securities sold. The Building Fund now amounts to \$58,099 15, which represents more nearly its actual value.

Expenses of the Society for 1939 show a moderate reduction over 1938, and this reduction is due in large measure to your policy in not publishing yearly a *Directory of Fellows*, which resulted in a saving of \$1300, and to the less amount needed for expenses of delegates to the American Medical Association. Several committees, however, have spent considerably more than their budget allowances—a practice which the Treasurer hopes will be corrected in the future.

The Society ends 1939 with total assets, cash and securities, of \$191,157 64, showing, in spite of a write-off of \$8135, a small increase over 1938.

The Treasurer is glad of the opportunity to thank officers of the Society, the district treasurers and the office staff of the *New England Journal of Medicine* for their co-operation, and especially to thank his secretary for her continued help and loyal co-operation.

The Treasurer invites questions
CHARLES S BUTLER, Treasurer

APPENDIX NO 4

REPORT OF COMMITTEE ON FINANCIAL PLANNING AND BUDGET

The following appropriations are recommended for 1940

| | |
|--|----------|
| Salaries | |
| Secretary | \$3000 |
| Treasurer | 1000 |
| Executive assistant | 2500 |
| Editor of Journal emeritus | 1200 |
| Expenses of officers and delegates | |
| President and Vice-President | 500 |
| Secretary | 1500 |
| Treasurer | 450 |
| District treasurers | 2700 |
| Censors | 900 |
| Delegates to House of Delegates American Medical Association | 400 |
| Maintenance of Society Headquarters | 5000 |
| Shattuck Lecture | 200 |
| Cotting luncheons | 450 |
| Standing committees | |
| Arrangements | 1000 |
| Publications | |
| New England Journal of Medicine | 20 500 |
| Directory | 2000 |
| Membership | 10 |
| Financial Planning and Budget | 10 |
| Ethics and Discipline | 150 |
| Medical Education and Medical Diplomas | 200* |
| State and National Legislation | 1000† |
| Public Health | 100 |
| Malpractice Defense | 2000 |
| Permanent Home | 0 |
| Special committees | |
| Postgraduate Instruction | 1000 |
| Physiotherapy | 0 |
| Public Relations | 500 |
| Special appropriation | 500 |
| Cancer | 0 |
| Section of Obstetrics and Gynecology | 200 |
| Industrial Health | 50 |
| Boston Better Business Bureau | 50 |
| Returns to district societies | 5000 |
| Delegates to Pharmacopeial Convention Washington D C | 200 |
| | \$54,270 |

*Including expenses of delegate to annual congress at Chicago and prize offered to interns in Massachusetts
†Including expenses of delegate to annual congress at Chicago

JOHN HOMANS, Chairman

APPENDIX NO 5

REPORT OF THE COMMITTEE ON MEMBERSHIP

The committee recommends

1 That the following named eight fellows be allowed to retire as of December 31, 1939 under the provisions of Chapter I Section 5 of the by laws

Allen Edwin H., Boston
 Heald, Charles G., East Pepperell
 Landry Joseph N., Everett, with remission of dues for 1937 1938 and 1939
 Latham Benoni M., Mansfield, with remission of dues for 1939
 Maxfield George H., State Farm
 O Neil, Richard F. Boston
 Pratt, Charles A., New Bedford
 Swan Roscoe W., Holden

2. That the following named eight fellows be allowed to resign as of December 31 1939 under the provisions of Chapter I, Section 7 of the by-laws

Dexter Milton A., La Jolla, California
 Edwards, Hugh S., Atlanta, Georgia
 Forkner, Claude E., New York City
 Kasanin Jacob San Francisco California
 Prandle, Clair G., Providence, Kentucky
 Russell Amy E., Mayville, Rhode Island
 Woodward, William C., Washington D. C.
 Young Ward Gouverneur New York

3 That the following named thirty-five fellows be deprived of the privileges of fellowship under the provisions of Chapter I Section 8 Clauses a and b of the by laws

Abate, Frank J. Charlestown
 Abrahams, Edward T. Piusfield
 Ascolillo Hugo V., West Somerville
 Beaulieu Elmer J. Whitman
 Buckley James T. Worcester
 Butler Alfred W. Watertown
 Carella Joseph J., Quincy
 Coburn Fordyce, Wilton, New Hampshire
 Corbett, John R., Melrose
 Darrah Lee W. Northampton
 Gant, Julian C. Boston
 Hanlan, David E., Hyde Park
 Hill, William R. Philadelphia, Pennsylvania
 Israel Cyril Woonsocket, Rhode Island
 Keenan, James A. Roxbury
 Lovesey Burton E., Boston
 McClelland, Willis B. Franklin, Pennsylvania
 McNally, Daniel R., Pawtucket, Rhode Island
 O'Brien, Francis E. Haydensville
 O'Leary Joseph J. Newton
 Pappas, James P., Fort Adams, Rhode Island
 Phillips Richard B., Rochester, Minnesota
 Poluner Saul R., Camden, Maine
 Ritter Henry Springfield
 Salerno, Louis F., East Boston
 Schultz, Robert V., New York City
 Shine, Honora K., Holyoke
 Sullivan, John J., Dorchester
 Sumberg Norwood Elizabeth H., Monmouth Maine
 Talkington, Perry C., Philadelphia Pennsylvania
 Tiede, Joseph W. Dedham
 Walker John H., Muskogee, Oklahoma
 Walsh, Patrick H., Fall River
 Weiner Simeon, Worcester
 Weissman, Herman J. Rockland Maine

4 That the following named fourteen fellows be allowed to change their membership from one district society to another without change of legal residence, under the provisions of Chapter III Section 3 of the by law

From Essex North to Essex South
 Sidwell Doris M., Georgetown

From Middlesex East to Essex South
 Flockton Priscilla, Saugus

From Middlesex East to Middlesex North
 Payne, Edward A. North Woburn

From Middlesex South to Norfolk
 Browder Newton C., Somerville
 Parvey Benjamin Brighton

From Middlesex South to Suffolk
 Edwards, Edward A. Newton
 Garrey Walter E. Cambridge
 Miller R. Bretnay Cambridge
 Scudder Charles L. Brookline (formerly Sherborn)

From Norfolk to Middlesex South
 Dalrymple, Sidney C., Brookline

From Norfolk to Plymouth
 Pearson Grosvenor B. Foxboro

From Norfolk South to Plymouth
 Buck William E. Randolph

From Norfolk South to Suffolk
 Whitney Edward T., Quincy

From Plymouth to Norfolk South
 Woodward, Appleton C. Stoughton

5 That the following named three fellows be recommended for affiliate fellowship in the American Medical Association

Chenery William E. Boston
 Felch Lewis P., Boston
 May James V. Watertown

APPENDIX NO 6

REPORT OF THE COMMITTEE OF ARRANGEMENTS

The Committee of Arrangements wishes to report that it has completed the program and plans for the forthcoming meeting of the Massachusetts Medical Society May 21 and 22, to be held in Boston at the Copley Plaza Hotel.

All the out-of-town guest speakers have accepted the invitation extended to them and the program has been completed.

The Committee of Arrangements is asking for a budget of \$1000 which should amply cover our needs this year

AUGUSTUS THORNDIKE JR. Chairman

APPENDIX NO 7

REPORT OF THE COMMITTEE ON PUBLIC HEALTH

The committee has continued its weekly broadcasts, "Green Lights to Health" on Wednesdays at 4 p.m. through the courtesy of WAAB. The program has been completed through March. There is a good demand for the mimeographed copies of these talks, and there is reason to believe that they are serving their purpose of educating the public in matters of health

A few months ago the President received a letter from one of the members suggesting that the Society, at the time of its annual meeting, provide an exhibition illustrating matters of health for the benefit of laymen. Such exhibitions have been held by the Illinois State Medical Society and a few other state and county societies under the name of "Hall of Health." These apparently have been very successful and have had a large attendance.

The subject was referred by the President to the Committee on Public Health. We have obtained considerable information as to the various 'Halls of Health' which have been held, and have discussed the advisability of the Society undertaking such a project. While on the whole we are favorably impressed with the idea, it seems to us a very large undertaking which would require long preparation in advance. Obviously there would not be time between this meeting of the Council and the annual meeting in May to get the necessary exhibits prepared.

It has seemed wise however, to bring this matter to your attention at this time—not for discussion or action now, but in order that the members may give the subject some thought before it is brought up at some subsequent meeting.

The expense to the Illinois State Medical Society for its 1939 "Hall of Health" was about \$1500, and there is every reason to believe that the expense to us would be no less. If the Society has that amount to spend on health education we ought to consider whether there are other methods which would yield larger returns from a similar expenditure.

At the last meeting of the Council the resolution of Dr. Landesman with reference to prenuptial examinations was referred to the Committee on Public Health. On this the committee submits the following report:

The committee recognizes the importance of the resolution submitted by Dr. Landesman. We feel that, in a premarital examination, interest should not be centered merely on the detection of syphilis and gonorrhea but should include a careful history and physical examination in order to establish a diagnosis of health or disease. Marriage and pregnancy present problems in many diseased conditions, and a knowledge of the facts by both contracting parties should be helpful in planning a successful marriage. We believe that both parties should be informed of the results of the examination.

The committee suggests the adoption by the Council of a resolution which is a slight modification of Dr. Landesman's, as follows:

RESOLVED, That in the opinion of the Massachusetts Medical Society all individuals about to be married should be required to have a thorough medical examination, including a serological test for syphilis, and the information obtained should be made available to both the contracting parties.

FRANCIS P. DENNY, *Chairman*

APPENDIX NO 8

REPORT OF THE COMMITTEE ON CANCER

The past year has seen continued satisfactory functioning of the educational campaign sponsored by the Massachusetts Medical Society and the Massachusetts Department of Public Health. Somewhat over 300,000 persons have been reached in this way. The average period of delay between onset of symptoms and beginning of treatment has continued to diminish.

It has been a fundamental part of the policy of the ed

ucational work in cancer that it should be done with the aid of physicians of the community where the work is going on. This policy has worked out satisfactorily in past years, and the co-operation of the various physicians has been so generous that it will be continued.

The system of consultation clinics at the state-aided cancer clinics has functioned satisfactorily and continued to prove popular, as evidenced by the large attendance of physicians at these meetings. It is planned that they be continued during the coming year.

The American Society for the Control of Cancer is studying the possibility of rather drastic changes in its organization in Massachusetts, feeling that the field of education is being better covered by existing agencies than they would be able to cover it. They are considering the possibility of building up an organization to raise funds for cancer research and to supplement the work of hospitals equipped for the care of indigent cancer patients.

A joint committee, consisting of representatives of this committee, the American Society for Control of Cancer, and the Massachusetts Department of Public Health, is editing a series of articles for a *Handbook on Cancer* which will be distributed without charge to the practitioners of the State. This will be financed in part by a federal grant and in part by the Massachusetts branch of the American Society for the Control of Cancer.

The month of April will again be set apart this year by presidential proclamation as a Cancer Control Month.

The committee wishes particularly to thank Dr. Herbert L. Lombard, director of the Division of Cancer, Massachusetts Department of Public Health, and a member of the Council, for his earnest and successful efforts to serve the interests of the practitioner of medicine and at the same time to aid him in caring more effectively for his patients.

FRANKLIN G. BALCH,
ERNEST M. DALAND,
CHANNING C. SIMMONS,
PHILEMON E. TRUESDALE,
SHIELDS WARREN, *Chairman*

APPENDIX NO 9

REPORT OF THE COMMITTEE ON POSTGRADUATE INSTRUCTION

The Committee on Postgraduate Instruction has continued to co-operate with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau in presenting extension courses. This past fall the courses were given in the following places:

| DISTRICT | PLACE |
|-----------------|-------------|
| Barnstable | Hyannis |
| Bristol North | Taunton |
| Bristol South | New Bedford |
| Essex North | Lawrence |
| Essex South | Salem |
| Middlesex East | Melrose |
| Middlesex North | Lowell |
| Worcester | { Milford |
| | { Worcester |
| Worcester North | Fitchburg |

Courses will be presented in the other districts this spring; a final report on the extension courses will be given at the meeting of the Council during the annual meeting next May.

The Executive Committee co-operated with representa

ties of the medical societies of Maine New Hampshire, Vermont and Rhode Island in organizing and presenting the second New England Postgraduate Assembly on October 31 and November 1 1939. An interesting program was given by the following guest speakers to whom we are greatly indebted:

Dr. Jesse G. M. Bullowa New York City
 Dr. Benjamin W. Carey Detroit
 Dr. Lewis A. Conner New York City
 Dr. Eldridge L. Eliason Philadelphia
 Dr. Albert C. Furstenberg Ann Arbor
 Dr. Roscoe R. Graham Toronto
 Dr. Charles C. Higgins, Cleveland
 Dr. Harvey B. Matthews, Brooklyn
 Dr. James S. McLester Birmingham
 Dr. Joseph Earle Moore, Baltimore
 Dr. Maurice C. Pincoffs Baltimore

The attendance at the assembly was 776 as follows:

| | |
|---------------|-----|
| Massachusetts | 630 |
| New Hampshire | 47 |
| Maine | 40 |
| Vermont | 23 |
| Rhode Island | 21 |
| Connecticut | 7 |
| New York | 2 |
| Venezuela | 2 |
| California | 1 |
| Iowa | 1 |
| Nova Scotia | 1 |
| Pennsylvania | 1 |
| Total | 776 |

The attendance last year (1938) was 925 the unusually inclement weather during the first day and night of the assembly no doubt accounted for the drop in registration. On account of this smaller attendance and some unusual expenses there was a deficit of \$835.84. This amount was charged to the account of the committee. In 1938 the assembly made a net profit of \$125.00 which was turned over to the treasurer of the Society. The committee believes that the assembly is a good idea and that it will not ordinarily run at a deficit as expenses can usually be kept within the budget.

The chairman and secretary attended the third annual meeting of the Associated State Postgraduate Committees, held at St. Louis on May 17 1939 during the annual meeting of the American Medical Association. A permanent constitution and bylaws were adopted at this meeting. The secretary of the Massachusetts committee will continue to serve as secretary of the national organization.

The Commission on Graduate Education provided the sum of \$350 to finance the organization expense of the Associated State Postgraduate Committees, and the funds of the Massachusetts Medical Society which were advanced for this purpose have been repaid in full with the thanks of the other state societies. The next annual meeting of this group will be held in New York City during the meeting of the American Medical Association in June.

The committee makes the following recommendations that the postgraduate extension courses and the teaching clinics be continued in co-operation with the government agencies, as has been done in the past and that the committee be instructed to continue its co-operative activity with the other New England societies in presenting an assembly next fall.

FRANK R. ORLER, *Chairman*
 LEROY E. PARKINS, *Secretary*

APPENDIX NO 10

REPORT OF THE COMMITTEE APPOINTED TO SUPPORT AN APPROPRIATION BY CONGRESS FOR THE CONSTRUCTION OF A NEW BUILDING TO HOUSE THE ARMY MEDICAL LIBRARY AND MUSEUM

The committee has been active and in communication with a number of individuals, particularly Colonel Harold W. Jones, the librarian of the Army Medical Library. His last communication to us in December indicated that he did not believe "that it will be wise for your committee to take any positive action until we can give you some definite lines on which to proceed." In view of this, we are awaiting further instructions from him. He indicates that similar committees have been formed throughout the country and that the Army Medical Library "appreciates the action of the Massachusetts Medical Society and will not delay giving you definite information in the near future."

HENRY R. VIETS *Chairman*

APPENDIX NO 11

REPORT OF COMMITTEE APPOINTED TO STUDY THE PRACTICE OF MEDICINE BY UNREGISTERED PERSONS

At the annual meeting of the Council last June it was voted to approve the following resolution recommended by the chairman of the Committee on State and National Legislation: "Resolved That the President nominate and the Council of the Massachusetts Medical Society elect a special committee to study and have corrected so far as possible the practice of medicine by unregistered persons."

At the regular meeting of the Council last October this committee was duly nominated and elected. At first, the three elected were reluctant to accept this appointment both individually and as a whole, as they had all been publicly recorded in the past four years as opposed to further legislation until the present laws were thoroughly tried out as their findings might be considered biased. Furthermore, "registered physicians" and "unregistered persons practicing medicine" are all under the direct supervision of the State Board of Registration in Medicine, a board under the appointment of the Governor and his council and in no way responsible, directly to the Massachusetts Medical Society. As the secretary of the Board of Registration well said before the Council in February 1937 "It is the duty of the Board under the police power of the State to protect the people of the Commonwealth. The duty of the Board is not to protect against physicians but against unqualified practitioners. Presumably they [the physicians] can protect themselves, but the protection the Board exercises is on behalf of the people of the Commonwealth."

However after a preliminary survey of the problem and with due recognition of its handicaps, the committee believes that there are definite simple, constructive suggestions to offer which it adopted, can be to the benefit of the Board of Registration the medical profession and especially the people of the Commonwealth and the committee is therefore submitting its findings.

This whole question has apparently been raised because the Board of Registration in its campaigns for more legislation during each of the past four years has been emphasizing to the public in its annual reports that they do not know who is actually practicing medicine in Massa-

chusetts, and it is impossible for the law enforcing body to restrict practice to registered persons. The result is that there are probably a thousand unlicensed persons [not physicians] in the State, who are practicing medicine in some form, and it may well be that a considerable number are practicing under the licenses of deceased physicians.

No provision is made by the statutes for keeping the list up to date." Such disturbing statements by the Board, which has had the responsibility for forty-five years of protecting the public against unregistered persons practicing medicine, has compelled the committee to ask why the Board thinks men are practicing on dead men's certificates, and why they think that one thousand out of a probable total of eight or nine thousand are unregistered. Such conditions, if true, not only reflect seriously on the whole medical situation in Massachusetts, but also on the Board itself. Is the alleged condition due to a lack of funds, a lack of laws, or to a lack of enforcement of the present laws?

In considering these questions, the committee has consulted the statutes, the reports of the Board since 1916, the records of many city and town clerks, various municipal police departments, the stenographic reports of the statements of the secretary of the Board before the Council in 1937 and also those of the chairman of the Board in 1939. They have also consulted the narcotic regulations of the Internal Revenue Department, and have inquired of 'detail men' who visit the physicians in the various communities throughout the State. This committee is not considering what other states do or do not do. It is not considering whether or not the requirements for registration are good, bad or indifferent. It is not considering what constitutes the practice of medicine. It is considering only why so many unregistered persons are said to be practicing medicine.

Is there a lack of funds? According to the Board and the committee believes the Board's opinion justified, it is hampered by too little money for the proper running of a well kept office. The Board has no inspector or investigator of its own. It has part of the time of one investigator, but his salary is paid by another board. The financial recommendations of the Board have been pared by the legislature, although its expenses have always been less than its receipts, but the members have apparently been unable to convince the budget commissioner, the legislature and the governor of their needs. The receipts have exceeded expenses by \$90,000 since the Board was established in 1894, and during the past four years the receipts have been \$5000 a year in excess of expenses each year.

It must be borne in mind that all the receipts of the Board go into the general funds of the State Treasury, and none whatever are earmarked for the special use of the Board. The Board is entirely dependent on the legislature for its appropriations.

It seems to be customary to expect such boards to be self supporting, but it surely should be desirable to provide this medical board with sufficient funds to run the department efficiently. The committee believes that the lack of money is a part of the problem.

Is there a lack of laws? The intent of the present laws is obvious. Roughly, anyone practicing medicine or holding himself out as a practitioner without certificate of registration by the Board of Registration is punishable by fine or imprisonment or both. Of course, anyone practicing on a deceased physician's certificate is seriously amenable to the general laws as well as to the special medical laws.

Not only does a physician have to register with the Board, but he also has to register with the city or town

clerk wherever he may have an office or offices. Fines for failing to do so are mandatory and not optional. Furthermore, the city and town clerks must notify the Board of Registration in Medicine within twenty four hours of such registration, and these town clerks are also subject to mandatory fines. And still furthermore, the Board 'is required to keep a record of the names of all persons registered by it and of all money received and disbursed by it, and a duplicate shall be open to inspection in the office of the State Secretary' (Chapter 112, Section 4). The committee believes the laws are ample and have plenty of teeth.

Is there a lack of enforcement of the present laws? The Board states in its 1936 report that it received seventy-three complaints and that five were against unregistered persons. In other recent years complaints were received but no mention is made as to whether any complaints were against the unregistered.

This committee has devoted considerable attention to finding out how well Chapter 112, Section 8, is enforced. This section says that "no person shall enter upon, or continue in the practice of medicine within the Commonwealth until he has presented to the clerk of the town where he has or intends to have an office or his usual place of business his certificate of registration as a physician of the Commonwealth." The committee has made this study because this section was adopted by the legislature in 1917 on the recommendation of the Board itself, and today, a copy of this section is given each newly registered physician by the Board when he receives his certificate—so it may reasonably be considered good law. The penalties for failure to register with the town clerk are mandatory on both physician and town clerk, and it ought to be much simpler for the local authorities to check their own communities than for the State House to check the whole state. Any physician not registered with the town clerk is practicing illegally. The members of the committee have visited the twenty-two clerks in the following cities and towns whose total population exceeds one million inhabitants, or about 25 per cent of the population of the State.

| | | | |
|-----------|---------|----------|------------|
| Andover | Everett | Newton | Somerville |
| Arlington | Lowell | Plymouth | Wakefield |
| Brockton | Lynn | Quincy | Winchester |
| Brookline | Malden | Reading | Woburn |
| Cambridge | Medford | Revere | |
| Chelsea | Melrose | Salem | |

They did not include Boston, believing that conditions in Boston could be just as readily investigated as those in the surrounding cities and towns. The committee also regrets its inability to visit places more removed from the metropolitan area, but believes the conditions would be the same. They found that every city or town clerk had a carefully kept file of all physicians who had registered with him. A goodly number have gone far beyond the legal requirements, indexing and assorting so as to make the information more available. One clerk, when told what other town clerks were doing in indexing, said that his office would at once prepare such lists, as he believed any well-kept office ought to have them. Another clerk refuses to recognize birth and death certificates of new physicians unless they have registered as required. All send their duplicate copies at once to the Board as required by law. Some little annoyance was found because the Board furnished no blank forms either with or without expense, but merely advised the clerks that they believed the required blanks could be obtained from the Library Bureau, a private concern. Books of ten blanks each cost over ten cents a name. Few, if any, of the clerks could

recall any information furnished or sought by the Board, and the public practically never consulted the lists although open to public inspection. The committee has only the highest praise for the accurate, careful courteous way in which the town and city clerks have handled all these registrations, which might seem useless and perfunctory as at present handled.

The committee has also consulted a goodly number of police departments. In no case had the police been informed by the Board of the lists of local physicians in the town clerks' offices, nor had the Board even asked their co-operation or called their attention to Section 8. In fact in answer to inquiry as to what their departments would do about complaints regarding unregistered physicians, they replied that the question had not been raised before but that there was either a good medical society or reliable physicians in the community whose advice they would seek. Few if any had realized that they could easily determine whether a person was practicing legally or illegally merely by consulting his own town clerk's records.

This committee also went over the duplicate list required by law to be filed in the secretary-of-state's office and open to public inspection. Although the Board has been functioning for forty-five years no lists of registered physicians were on file up to 1931. For the years 1931 to 1938 inclusive, the yearly registrations had been filed on letter paper single spaced, and all were filed one to six years late. No addresses followed any of the names. In two of these years, the names were listed alphabetically. There were no lists for 1939. Although these lists were by law open to public inspection, they had never been consulted. Perhaps this is because the Board says that for the convenience of the public the information is given out in its office. The secretary-of-state's office merely files what the Board furnishes, and has no responsibility for the contents. The committee believes that such chaotic lists need no further comment.

At the Board's office, the clerks readily looked up various cards but said they could not be inspected by the public unless they waited for an obtained permission from the secretary of the Board as the records were not for public use. The clerk in charge said that the Board had but one alphabetical list of names of applicants, names of interns and students and so forth all merged in one alphabetical list with the more than 18,000 physicians registered since 1894. The deaths and removals—probably 10,000—were not placed in separate lists. The office clerks were not allowed to show the duplicate returns made by the city and town clerks, although the originals in the city clerks' offices were open to public inspection. No list or cards were kept showing the physicians registered in each city and town.

The office force apparently also handles the registration of nurses, which is in the same office, the secretary of the medical Board being also secretary of the nurses Board. As the nurses Board examines fifteen hundred nurses annually collects annual fifty-cent fees from over nineteen thousand registered nurses and also collects nearly \$1000 for certified statements the work of the medical Board becomes rather insignificant, in quantity at least, as compared with the other work in this small office.

To summarize, this committee finds that the laws are adequate that the income of the Board has covered expenses by over \$5000 in each of the last four years and that the income since 1894 has exceeded expenses by \$90,000. In spite of this, the Board has not yet convinced the legislature and the governor of its need of more funds for a well-conducted office. The committee further finds that the city and town clerks and the local police have not been

called on to co-operate with the Board in seeing that the unregistered persons in their immediate communities are reported a problem in which local authorities would be especially interested.

The committee further finds that no useful lists of registered physicians are open to public inspection at the State House and that the Board has no lists of the physicians arranged by cities and towns.

It is probably now apparent what the suggestions of this committee must be. They are simple and inexpensive, and can be carried out without inconvenience to the medical profession. The suggestions merely use the present dormant laws.

As soon as the Board arranges its finances so as to provide adequate cataloguing systems and as soon as it does its part in generous co-operation with the local authorities, then it will almost at once automatically establish a list of the active physicians of Massachusetts. It will also have for its private use another file of the "unregistered." What disposition is to be made of this "unregistered group" which the Board has been seeking, is a problem for which the Board is held directly responsible by the statutes but the committee believes that this illegal group is less numerous and less important than reported.

The Massachusetts Medical Society has 5189 members, or two thirds of the physicians in the State. The committee believes the Council can be of real service to the Board by urging all district societies and all individual members to make sure that they are registered with their city and town clerks and that they re-register whenever they move their offices, even within the same city. Furthermore, the Massachusetts Medical Society has an enviable reputation of long standing for supporting public-health and medical legislation, and this committee believes the Council can with propriety respectfully urge the Governor and his council to give serious consideration to the financial needs of the Board of Registration in Medicine.

The committee in closing expresses its appreciation of the many courtesies shown it by officials of the Society by various departments at the State House, by all local municipal officials interviewed and by others who have made valuable suggestions.

CHAPTER 112

Section 4 The board shall keep a record of the names of all persons registered by it and of all money received and disbursed by it, and a duplicate thereof shall be open to inspection in the office of the state secretary. The board shall make an annual report, including a statement of the condition of medicine and surgery in the commonwealth.

Section 5 The board shall investigate all complaints of the violation of any provision of sections two to twenty three, inclusive, or of section sixty five, so far as it relates to medicine or chiroprody, and report the same to the proper prosecuting officers.

Section 8 No person shall enter upon, or continue in, the practice of medicine within the commonwealth until he has presented to the clerk of the town where he has, or intends to have, an office or his usual place of business, his certificate of registration as a physician in the commonwealth, or, if it is lost, a certified statement issued by the board, setting forth all the material facts in the original certificate, and a fee of twenty five cents. Thereupon the clerk shall record the name of the owner of said certificate or certified statement, together with the date of record upon blanks approved by the board, said blanks to be so arranged that a duplicate carbon copy shall be made at the time of the original record. He shall keep the original as a part of his official records and it shall be open to public inspection. He shall, within twenty four hours after such

22 recordings, forward the duplicate to the board. Whoever practices or attempts to practice medicine without complying with this section, or whoever submits to a town clerk a false or fraudulent certificate or certified statement, shall be punished by a fine of not less than five nor more than one hundred dollars, and any town clerk who refuses or neglects to comply with this section shall be punished by a fine of not less than five nor more than ten dollars.

APPENDIX NO 12

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

At a meeting of the Committee on Public Relations, held on January 17, 1940, after a full discussion by the seventeen members present, it was voted (with one dissenting) to make the following report to the Council.

The Committee on Public Relations has again considered the matter of prepayment medical service plans, including that offered by Health Service, Incorporated.

It believes that any scheme to provide prepayment against medical costs for illness should offer an opportunity for all duly qualified physicians to participate if they choose. Whether this is on a state, county, district or municipal basis is immaterial. It believes that free-choice of-physicians should be maintained in order to continue present personal relations between physician and patient.

We are deeply cognizant of the fact that many people are asking, some demanding, a plan or plans for budget sickness costs. We appreciate the effort of Health Service Incorporated, in this direction, but believe that the success of its plan is seriously jeopardized by failure so far to give due consideration to many principles which we consider fundamental.

We believe, however, that the whole matter of prepayment health insurance is so much in the public mind and so important that any scheme should not be condemned without more careful study and that a special committee should be set up to study it. This committee should study the whole subject of prepayment sickness costs.

WE THEREFORE RECOMMEND THAT A SPECIAL COMMITTEE OF FIVE MEMBERS OF THE SOCIETY BE APPOINTED BY THE PRESIDENT TO STUDY THE VARIOUS MEDICAL-COSTS INSURANCE PLANS AND TO ENDEAVOR TO CARRY OUT THE VOTE OF THE COUNCIL OF APRIL, 1939, TO WIT

Voted, that the Massachusetts Medical Society to the initiative in the formation of a corporation, not profit in character, which shall seek to pay the medical care costs of patients,

THAT THIS SPECIAL COMMITTEE FURTHER BE AUTHORIZED TO CONFER WITH ANY GROUP PROPOSING TO SET UP A PLAN FOR MEDICAL-COSTS INSURANCE,

THAT THIS SPECIAL COMMITTEE BE EMPOWERED TO EMPLOY LEGAL COUNSEL AND THAT FUNDS NOT TO EXCEED \$500 BE APPROPRIATED FOR THIS PURPOSE, AND

THAT THIS SPECIAL COMMITTEE SHALL REPORT TO THE COUNCIL THROUGH THE COMMITTEE ON PUBLIC RELATIONS

THE COMMITTEE FURTHER RECOMMENDS THAT PUBLIC RELATIONS RELATING TO THESE MATTERS BE UNDER THE DIRECTION OF THE PRESIDENT AND SECRETARY OF THE MASSACHUSETTS MEDICAL SOCIETY.

ELMER S BAGNALL, *Secretary*

APPENDIX NO 13

 REPORTS OF COMMITTEES APPOINTED TO CONSIDER
 RESTORATION TO FELLOWSHIP

Restoration to fellowship was recommended for the following former members

Gerard Cote Salem (Committee Charles L. Curtis,
 John G. Adams and Horace Poirier)

Hymen S. Queen, Brookline (Committee Frank S.
 Cruickshank, Charles J. Kichham and Frederick
 Reis)

APPENDIX NO 14

 COMMITTEES APPOINTED TO CONSIDER PETITIONS
 FOR RESTORATION TO FELLOWSHIP

The following committees were appointed to consider the petitions for restoration to fellowship of the following five former members

For Lionel M. Cole Pittsfield
 Maurice S. Eisner, Garvey Adeson and George M.
 Slipton.

For Paul R. Donovan Revere.
 Earle M. Chapman, Harold L. Musgrave and George
 L. Gately

For Roland O. Parris, Falmouth
 John I. B. Vail John P. Nickerson and Julius G.
 Kelley

For H. R. Record Quincy
 Cornelius J. Lynch, Cornelius A. Sullivan and Wil-
 liam J. MacCausland.

For Frank J. Vaccaro Pittsfield
 Harry H. Bard, Newell N. Copeland and Modestino
 Crisnetello.

APPENDIX NO 15

 RESOLUTION PRESENTED BY DR. ELMER S. BAGNALL

WHEREAS, There is considerable confusion among the members of the Massachusetts Medical Society as to their proper place in the administration of compensable medical care to recipients of relief under the various welfare laws of the Commonwealth and under the ordinances and regulations of the cities and towns of the Commonwealth now then be it

RESOLVED, That the president of the Massachusetts Medical Society appoint a committee of five fellows for the following purposes to assemble information, investigate, study and report to the Society as soon as may be, on the proper place of physicians in the administration of medical care to persons receiving Old Age Assistance, Soldiers Relief and all other forms of welfare or assistance provided for by law and to be compensated therefor by the city or town responsible for the furnishing of such aid, relief or welfare to said person.

APPENDIX NO 16

 RESOLUTION PRESENTED BY DR. EDMOND F. CODY

WHEREAS, Morbid anatomy is the foundation of medical knowledge and

WHEREAS, The lessons derived therefrom constitute a most powerful postgraduate study and

WHEREAS, The number of postmortem examinations now obtained both in hospitals and outside is deplorably small therefore, be it

RESOLVED That the Massachusetts Medical Society appoint a committee to study the subject with a view of petitioning the General Court to increase the facilities for postmortem examination by making available the services of one well-trained pathologist in each district of the Massachusetts Medical Society

REPORT ON MEDICAL PROGRESS

NEUROSURGERY

DONALD MUNRO, M.D *

BOSTON

THE passing of 1939 marks the end of an era in neurological surgery. Raised, under the aegis of Horsley and Kocher, from the field of experimental surgery to the dignity of an important surgical specialty under the world leadership of Cushing, it is now obliged to proceed farther along the road to maximum usefulness without the guidance of either an actual or titular head. The deaths of Frazier and Cushing and the retirement of Elsberg leave the direction of American neurosurgery to their many pupils. Coincidentally a significant change has taken place in its type and extent. Its scope is no longer limited to tumors of the central nervous system and pain in the face. It has become plebeian. Its greatest concern nowadays is with the effects of trauma, and its greatest asset is an increasing knowledge on the part of the general surgeon of his own possibilities and limitations in this particular field. Among other things, its practitioners, like the general surgeon, must be willing to consult with specialists in otology, rhinology, dentistry, ophthalmology, urology, neurology and orthopedics. They must have some knowledge of the fundamental physical processes, and must be prepared to deal with the ordinary preoperative and postoperative and emergency surgical problems as they arise. It is becoming increasingly apparent that the day of the neurosurgical giant who was omniscient in all the specialties has passed. A glance at the classified references at the end of this review emphasizes this, and re-emphasizes the equal necessity of realizing that neurological surgery today includes much more than the surgery of central-nervous-system tumors.

ANATOMY AND PHYSIOLOGY

Two papers on the circulation of the spinal cord should be studied in all their detail by every surgeon who deals with the spine and its contents. They are by Suh and Alexander¹ and Herren and Alexander,² and describe the architecture of both the arterial and venous circulations. Their demonstration of the importance of certain radicular arteries and veins cannot be overestimated. Attention should be called more particularly to those ventral arteries that accompany the third and fifth cervical, the tenth thoracic and the second lumbar roots, the dorsal arteries that accompany the sixth

thoracic and the third lumbar roots, and the veins that run with the fourth and fifth cervical, the first, fifth, eighth and ninth thoracic and the first and fifth lumbar roots ventrally, and the third cervical and first, ninth and twelfth thoracic roots dorsally. The significance of this knowledge in relation to thrombosis, root or tract section and cord injury is immeasurable. Of some importance also is a paper by Schajowicz³ on the microscopic structure and pathology of intervertebral disks in the young. The development and growth of these surgically popular structures are well presented from the histological point of view.

More and more attention is being paid to the maintenance of a proper water balance in all surgical patients. This is especially necessary in the neurosurgical group because of the maximum alterations produced in the cerebral circulation and intracranial pressure by what are often thought to be insignificant changes in fluid intake. However, there is as yet no completely satisfactory method of testing for the presence of fluid imbalance. I have demonstrated that toxic dehydration in craniocerebral injuries is invariably accompanied by a dropping of the intracranial pressure to artificially low levels, but this identifies only the late stages of the process. Elkinton, Gilmour and Wolff⁴ made a study of 10 surgical patients from the point of view of their water balance. As a result, they concluded that the "electrolyte and water balance in surgical patients may be evaluated fairly accurately by simultaneous determinations of hematocrit value, plasma protein, chlorides and carbon-dioxide combining power." The total base is approximated from the latter two figures. "Hemoconcentration is an indication of serious depletion of the extracellular water," and "a falling total-base concentration indicates extracellular base depletion." A simpler method is that recommended by Hopps and Christopher.⁵ They restudied the old McClure-Aldrich test in this connection, and in 7 cases found it to be "a sensitive and reliable index to the state of hydration" and "a useful guide to the optimal fluid administrations provided the electrolyte balance was taken into consideration." The test is done by the injection of 0.2 cc of an 0.85 per cent solution of sodium chloride intradermally at standard points through standardized equipment. Unquestionably, neurosurgeons and general surgeons doing neuro-

*Assistant professor of neurological surgery, Harvard Medical School; surgeon-in-chief for neurological surgery, Boston City Hospital.

logical surgery should pay greater attention to such fundamental work.

INJURIES TO THE CENTRAL NERVOUS SYSTEM

Craniocerebral Injuries

It can be taken as almost axiomatic that new surgical technical procedures will eventually prove to be rediscoveries. Strayer,⁶ in a fascinating article entitled "Augustin Belloste and the Treatment for Avulsion of the Scalp," traces back to 1696 the development of the so-called modern method of early trephination of the outer table in the treatment of a denuded skull. "Belloste's significant contribution was to state that small perforations of the outer table should be made at the primary dressing of the wound, thus entirely avoiding exfoliation or sequestration. Surgery of today, and more particularly that of the specialities, profits by such insults to its ego."

A study of the x-ray characteristics of fracture of the cranial vault and the probability of demonstrating these fractures has been made by Santagati in Italy. It emphasizes the essential and incontestable inaccuracy of this procedure and mentions such causes of diagnostic error as thickened wound edges, defects in the film, arterial and venous grooves, and supernumerary and usual suture lines; it might well have included the indispensability of stereoscopic visualization of the suspected area. A greater appreciation of the roentgenological possibilities and deficiencies in relation to the skull would be of material aid to both pathologists and roentgenologists.

Subdural hematomas continue to hold the interest of the neurosurgeon, almost to the exclusion of any of the other varieties of acute cranio-cerebral injuries. One of the more extraordinary side effects of this interest is the persistence with which certain authors draw sweeping conclusions from an entirely inadequate number of cases, and the willingness with which certain journals allow such authors the use of their pages. Were the subject anything but subdural hematoma, articles such as that written by Coblenz⁷ and published in *Surgery* and editorials such as that⁸ which appeared in the *Journal of the American Medical Association* would hardly be accepted. The solemn statement by the former of trite conclusions based on an experience that is limited to 14 cases cannot be justified and reflects on the author. This is the truer when one realizes that there are already in the American literature numerous more complete reports on the same subject. Moreover, the latter present conclusions based on individual experience with hundreds of cases.

On the other hand, the description of relapsing juvenile chronic subdural hematomas by Da-

vidoff and Dyke⁹ and Ingraham and Heyls¹¹ study of subdural hematoma in infancy and childhood are invaluable and should receive close attention. The former point out the danger, in children, of new bleeding into the sac of an old previously unrecognized cerebral subdural hematoma and describe the diagnostic criteria. The latter call attention to the fact that the membrane formed around subdural hematomas occurring during the stage of brain growth must, if possible, be removed, or at least split vertically and horizontally, if resultant pressure atrophy of the underlying cortex is to be prevented.

Three cases of traumatic enophthalmos have been reported by Rand and Reeves.¹² According to them, only 164 cases of this interesting and rare condition had been collected up to 1930. They believe that many slight examples of this condition escape observation, especially in the earlier stages. It must be differentiated from facial hemiatrophy, phthisis bulbi and microphthalmos. No treatment is of avail, and further recession occurs in many cases. Usually the visual acuity remains unchanged, but in a few cases vision becomes impaired even to the point of blindness.

In the past year the late effects of cranio-cerebral injuries have received attention. An outline of the care necessary during the convalescent period immediately following hospitalization has been described by Munro.¹³ Grant and Norcross¹⁴ have reviewed the problem of repair of cranial defects by cranioplasty, and recommend a modification of the König-Müller operation. This implies an osteoperiosteal homologous graft from the outer table of the skull. The article is well documented, and the important point is made that cranioplasty has definite indications (such as convulsive seizures and neurosis) beyond the closure of a defect. Heyman¹⁵ reports the results of 280 operations on 176 patients suffering from cerebral spastic paralysis. These cases were picked as suitable from a larger group of 1500. Surgery is used only in addition to and as supplementary to education, muscle training, occupational therapy and so forth. The paralyses were all the result of birth injuries. The procedures used were in general orthopedic in type, such as motor-nerve resection, tendon transplantation and arthrodeses. The end results were poor on the upper extremity and good on the lower. Munro¹⁶ considers the diagnosis and therapy of so-called post-traumatic neurosis. He emphasizes the indispensability of hospitalization previous to diagnosis and advice as to therapy, and holds that exploratory diagnostic trephination is not only justifiable but in many cases essential. An end result study of 47 such cases in which this procedure alone made possible the diagnosis of

*Assistant professor of neurological surgery, Harvard Medical School; surgeon-in-chief for neurological surgery, Boston City Hospital.

fect as amphetamine but less in amount when used alone, and enhances the effect of amphetamine when used in combination with it.

What is otherwise a most valuable paper by Coleman and Meredith⁴⁴ is spoiled by their attempt to analyze therapy and end results of all levels of spinal-cord injury at once, and more particularly by their statement that the immediate onset of total paralysis after a spinal-cord injury predicates and justifies the diagnosis of transection of the cord. This is not necessarily so, and ignores the well known effect of the presence of spinal shock in such injuries. I and doubtless many others have plenty of patients actively earning their own living who as the result of a cervical spinal-cord injury were totally paralyzed from the shoulders down immediately after their injury. Fractures of the atlas are studied in detail in a report made by Plaut.⁶ Unfortunately, the paper includes patients with and without associated cord injury, and is chiefly made up of reports of 99 cases extracted from the literature, there being only 6 of his own. However his statements that in recent years fatalities occurred in only 9 per cent of these fractures, and that an overwhelming majority of the patients recovered to full occupational activity, are encouraging. Watson Jones's⁴⁵ paper on the postural reduction of fractures of the spine should be read with a critical eye because, again, the cases with cord injury have not been sufficiently differentiated as to method of treatment and end results from those without it. Certainly my experience convinces me that such a rapid and forceful method of hyperextension as Watson-Jones advocates for the reduction of deformities in the thoracic and lumbar spines will lead to nothing but trouble if there is any significant cord damage associated with the bone lesion. George's⁴⁶ paper on 271 patients with spondylolisthesis and 42 with spondylolysis should be brought to the attention of surgeons interested in the effects of spinal injuries. He presents evidence "which tends to confirm the theory that the lesion in spondylolisthesis and spondylolysis is essentially a congenital developmental defect in the interarticular portion of the laminae of the involved vertebra rather than the result of trauma.

INFECTION OF THE CENTRAL NERVOUS SYSTEM

No essential change in the therapy of meningitis and brain abscess has developed during the past year. The problem of osteomyelitis of the skull has been summarized by Mosher⁴⁷ in an article that must be regarded at this time as the final pronouncement relative to this difficult and dangerous disease. This should be required reading for all

surgeons, and particularly for those specializing in nose and throat and neurological surgery. The importance and possibility of early diagnosis, the necessity for wide excision of the diseased bone, the inclusion in the excision of 2 to 4 cm. of what appears to be normal bone and the ultimate conservatism of what the operator thinks is unduly radical surgery cannot be emphasized too strongly or repeated too often.

The study of spinal infections has this year been concentrated on osteomyelitis of the vertebrae and its complications. Turner⁴⁸ reports 12 of his own cases and adds 71 from the literature. The mortality ranged from 50 to 70 per cent, and extension of the infection to the spinal canal (epidural spinal abscess) was an infrequent but fatal complication. As in uncomplicated epidural spinal abscesses, Turner notes the frequency of skin lesions as an etiologic factor. Active surgery, with drainage of the abscesses and removal of the accessible involved bone, is as essential as the later treatment that is designed to prevent deformities.

Cairns⁴⁹ in a study of 968 intracranial operations considers the incidence, cause and prevention of wound infection in the operating room. He re-emphasizes the harm of tissue necrosis caused by too tight sutures, inadequate blood supply caused by a too narrow pedicle in the flap operations and the seriousness of streptococcal droplet infection. The last should receive more attention than it has. As Cairns and others have stated, and as I have also found true in my own operating room, the ordinary non-impervious tightly fitting mask made of gauze and pulled tightly over the nose and mouth gives so little protection as to be more of a liability than an asset. On the other hand, Cairns reports prevention of this complication by the use of a mask in which cellophane is incorporated. This has been my experience also after five or more years of exclusive use of such a mask. The mask is made of two pieces of fine mesh gauze 10 inches square. Between them, and basted into place in such a way as to come in contact with one whole side and parts of two others, is stitched a piece of blue cellophane 9 by 6 inches. Blue cellophane is used because its visibility is greater against the white gauze and it can be sewed in place with greater ease. Nine inch tapes are sewed to each corner. The mask is put on with the cellophane covering the mouth and nose. The upper edge is pushed under the lower edge of the operator's glasses, if he wears them, and the upper tapes are carried over the ears, pulled tight and tied beneath the occiput. The tapes from the lower corners are tied loosely behind the neck in such a way as to cause the lower

unencysted fluid subdural hematoma is presented Gardner¹⁷ writes about encysted subdural hematomas as seen late after acute injury Both unencysted and encysted types are end results of previously unrecognized and untreated acute subdural hematomas The unencysted hematomas were made up—in the acute stage—of large amounts of cerebrospinal fluid and little if any blood, while the latter—in the same stage—were composed largely of blood with which was mixed little or no cerebrospinal fluid Because of their respective compositions, only the latter developed a membranous envelope, and of these, only the clots in which liquefaction took place faster than organization manifested themselves later as encysted

Spinal Injuries

The proper understanding and consequent proper care of the paralysis of the bladder that is associated with any significant degree of spinal-cord injury continue to be the most important factors in the attempts being made to reduce the mortality of spinal injuries The physiology was originally first adequately covered by Denny-Brown, and more recently has been restated by McLellan¹⁸ with certain modifications incident to disease of the nervous system This book repeats what had already been recognized by those with experience enough to justify their expressing an opinion on the subject, when the author states that paralysis of the bladder following nerve injury or disease passes through recognizable phases of physiologic activity on its way to recovery These phases are easily but exclusively identifiable by cystometry There can therefore be no excuse for such a statement as that made by Hinman,¹⁹ that the effect on micturition is retention, overflow, incontinence, automaticity and true incontinence If one is to write on a vital subject, such a failure to keep up to date is inexcusable, and is matched only by the author's extraordinary recommendation of non-catheterization with manual expression and cystostomy as the proper therapy for bladders of patients with spinal-cord injuries

The chance of non-infection of the bladder in spinal-cord injuries is so small as to be of no significance, and it can be accepted as fact that all such patients have a bacteriuria within seventy-two hours of the time of the injury, particularly if they have been catheterized This bacteriuria is harmless if residual urine is never allowed to collect and remain undisturbed Nevertheless, the neurosurgeon in charge must have some knowledge of modern chemical urinary antiseptics Ezickson²⁰ studied 25 patients with urinary sepsis whom he treated with sulfanilamide His best results

were in cases in which *Bacillus coli* and the streptococcus were found, and his failures were with *B. proteus*, Friedlander's bacillus and *B. pyocyaneus* He rightly insists that a complete urological study be carried out before administering the drug Schar²¹ reports some interesting and fundamental work on urinary antiseptics He studied the ability of the bladder of animals and of man to absorb and excrete various chemicals Among other things, he found that anesthetic substances, urine, water and the substances present in urine (especially urea) were able to pass through the bladder wall in both species All his experiments on man showed that an ulcerated bladder is capable of absorbing three times the amount absorbed by a normal bladder From these and other data he justly concludes that in choosing substances to be used for bladder irrigation or instillation, the toxicity, absorbability and concentration of the drug, as well as the capacity and condition of the mucous membrane, must be carefully considered A study of the effect of surgery on the pain of spastic infected bladders is reported by Nesbit and McLellan²² They demonstrated that sympathectomy relieved pain in such cases by controlling "the spasm of the internal sphincter and perhaps other parts of the bladder musculature" This is in agreement with Denny-Brown's and my findings that the presacral connections carry only sensation of pain and not other afferent stimuli Nesbit and McLellan hold that presacral neurectomy alone and without the additional exeresis of the lateral sacral sympathetic ganglionated chain will relieve as much pain as does the more extensive dissection This denervation, moreover, does not render the bladder insensitive to pain that originates from causes other than spasm of the vesicle outlet and detrusor mechanism Such conservative sympathectomy "should be resorted to in only those patients in whom that pain is clearly demonstrated to result from spasm of the vesicle outlet," and "was not shown to cure the lesions of Hunner ulcer" Surgeons who expect to change any other bladder activity or sensation by presacral neurectomy should consult this article and its bibliography before doing the operation Loman, Greenberg and Myerson²³ have produced a valuable paper on the effects of certain drugs on the urinary tract, with suggested clinical application They find that Mecholyl causes the kidneys, ureters and especially the bladder to contract. Prostigmin alone has no effect, but enhances the effect of Mecholyl Amphetamine (Benzedrine) gives exactly the opposite effect to that of Mecholyl, the kidneys, ureters and especially the bladder all relaxing and dilating Atropine has the same ef

Schnitzer, Cutler, Bailey and Vaughan⁴⁰ have written on the place of irradiation in chromophobe adenomas and acromegaly. They conclude that irradiation should be tried for the chromophil as well as for the chromophobe adenomas before surgery is used and unless there is imminent danger of permanent visual impairment. This conclusion re-emphasizes the best present-day opinion on this matter, and to it need only be added the warning that the surgeon-in-charge is lax if he does not require a patient undergoing such treatment to have his visual fields checked every six months or oftener. An authoritative and more general approach to this subject will be found in the series of research publications on an investigation of the most recent advances relative to the anatomy, physiology and general considerations of clinical importance of the pituitary gland. These are available in the form of a bound volume,⁴¹ and emanate from the Association for Research in Nervous and Mental Diseases.

Acoustic Neuromas

The problem of whether to do a total extirpation of an acoustic neuroma and give the patient a complete facial palsy or an intracapsular enucleation, leaving the innervation of the face intact but subjecting the patient to the certainty of a recurrence of the tumor, is still under discussion. Horrax and Poppen⁴² report in detail on a series of 35 cases. They advocate total extirpation on account of a lower operative and total mortality and because their mortality in the recurrent cases has been high. Gardner⁴³ and others subscribe to this point of view. Probably the best person to decide is the patient!

Spinal Tumors

The diagnosis and therapy of spinal tumors appear to be fixed. A paper by Boldrey and Elvidge⁴⁴ on dermoid cysts of the vertebral canal adds 3 cases to a collected total of 37. The cysts are slowly progressive and do not produce compression until the second, third or fourth decade. Since their removal is usually incomplete, they tend to recur. Pilonidal sinus is frequently associated with them. Horrax and Henderson⁴⁵ report a case in which there was an encapsulated intramedullary tumor which extended the whole length of the cord. To remove it required two operations—the removal of all spinous processes and laminae from the axis through the second lumbar vertebra, as well as the splitting of the spinal cord down the middle of its posterior surface for its full length. As the authors say, a single case report is usually valueless, but this case merits attention as much for the sake of the surgical procedure as for the tumor.

X ray Therapy

Uncertainty as to the possibilities and limitations of x ray therapy of brain tumors is so widespread that reports such as that written by Nessa⁴⁶ are of great value. He details the results obtained by irradiation in a series of 44 cases in which the diagnosis was proved by biopsy or necropsy. It would appear from this study that x ray therapy in certain cases of brain tumor may be distinctly helpful, and that the dosage should be materially increased.

PERIPHERAL NERVOUS SYSTEM

Aird and Naffziger⁴⁷ have published the results of some interesting work on the regeneration of peripheral nerves. The experiments were made on dogs and were well controlled. The results led these authors to believe that very satisfactory recovery of muscular function can follow the anastomosis of small proximal to large peripheral nerves, that synergistic muscle groups may be successfully reinnervated by the anastomosis of the nerve supplying one of those muscles to the peripheral portions of the nerves innervating both groups of the synergistic muscles, and that the flexor muscles of the leg showed a better functional result than the extensor. The widespread possible clinical application of this work—as in poliomyelitis—is obvious.

Nerve injuries associated with supracondylar fractures of the humerus in children were studied at the Boston City Hospital by Bailey.⁴⁸ He reports 71 such fractures seen in three years, with 6 cases complicated by nerve involvement. Four of the 6 cases had radial, 1 median and 1 radial median and ulnar nerve involvement. From a study of these cases Bailey concludes that the paralysis may occur either as the result of the fracture or from trauma during reduction, that the radial nerve is the most commonly affected, that it is usually not severed but rather contused, and that beginning return of function, if it is to occur, may be expected in the paralyzed muscles within eight weeks, with complete return in four to ten weeks. Reductions should be gentle, weakened muscles must be supported, physiotherapy instituted early and exploration of the nerve undertaken if no recovery of function is manifest within twelve weeks. In view of the fact that these cases are usually seen by either the general surgeon or the orthopedist, whose main interest is in the fracture, the importance of this paper can not be overestimated. The possibility of nerve injury in association with all fractures of the lower three fourths of the humerus should receive the same degree of attention that the possibility of nerve injury in association with the head of the

fibula does. Equal care should be taken in the application of circular splinting material, adhesive plaster, bandage and so forth, and an equal anxiety as to the possible deleterious effect of such splints should be exhibited at all times. Above all, no circular plaster should be put on these fractures without making provision at the time of application for a cock-up support of the wrist and hand, whether or not evidence of nerve injury is present. Exploration or repair of the nerves of the extremities should not be undertaken without a full knowledge of the technical requirements of such a procedure. Among the more essential of these is burial of the exposed part of damaged peripheral nerves, whether or not sutured, in muscular tissue, if later interference with return of function from scar contraction at the operative site is to be avoided.

The treatment of facial paralysis is well covered by Cleveland⁴⁹. He reviews the literature from 1932 to 1938, and covers all phases of this difficult problem thoroughly. He reaches no conclusions, however, and the reader must draw his own. Anyone having the responsibility of the treatment of facial paralysis should not fail to consult this article in detail before making up his mind as to the best therapeutic method to be applied to the individual case. Brown's⁵⁰ article on the utilization of the temporal muscle in the correction of facial palsy should also be consulted.

SYPHATHETIC AND PARASYMPATHETIC NERVOUS SYSTEMS

What used to constitute the bulk of neurosurgical literature has now simmered down to a number of articles that is commensurate with the practical possibilities of the surgery of the sympathetic and parasympathetic nervous systems. Among the most practical opportunities for therapy along this line is the modern treatment of hyperhidrosis of nervous origin, as described by White⁵¹. Such appropriate surgery returns to otherwise permanent invalids the power again to earn their living and to mingle freely with society. Its value cannot be overestimated. Meigs⁵² re-emphasizes the effect of presacral neurectomy on dysmenorrhea. He confirms my earlier observations that the effect of this denervation on bladder activity is nil if limited to the hypogastric plexus itself. While his conclusions in general are sound and should guide the application of this specialized operation, his description of the physiology of this plexus leaves much to be desired, and, as has recently been demonstrated, is wrong in many of its major concepts.

Denervation of the carotid sinus for the so-called carotid sinus syndrome has been described from

France by Léger⁵³. His suggestion that novocain be injected into the intercarotid notch before stripping the vessels is sensible. According to my experience, however, the length of vessel that Léger strips on either side of the fork is inadequate. His claim that the field of usefulness of this procedure embraces epilepsy (*sic*) is untenable, unless some more accurate diagnostic classification is used. His and Rovenstein and Cullen's⁵⁴ preoccupation with the type of anesthetic to use in these cases seems somewhat unnecessary. In 14 of my cases I have used ether given by the drop method on an open mask and usually preceded by a small dose of Avertin, and have had no difficulties of any sort. However, I am as opposed as are these authors to the use of local anesthesia in such cases.

A note by de Takats⁵⁵ on the use of acetylcholine as a diagnostic test in cases of megacolon deserves more attention than its length would apparently warrant. As a stimulant of the parasympathetic outflow, this use of acetylcholine will doubtless lead to a greater efficiency in the diagnostic and therapeutic study of large numbers of the diseases of the bladder and lower bowel.

VASCULAR SYSTEM

The elucidation of the problem of essential vascular hypertension proceeds, perhaps not apace, but rather in a slower and more orderly manner than heretofore. Heymans⁵⁶, in a short report, has a concise statement of his experimental approach to this subject. He includes his pertinent physiological findings as well as his own and his several collaborators' conclusions. He is refreshingly moderate and judicious in his statements. Surgically, a series of twelve cases is reported from France by Paliard and Étienne-Martin⁵⁷. Davis and Barker⁵⁸ describe their findings in a group of similar cases, as well as their experimental work on the combination of surgery and the therapeutic administration of potassium sulfocyanate. From the medical point of view, Robinson and O'Hare⁵⁹ also discuss potassium sulfocyanate therapy. So far as the individual patient with hypertension is concerned, methods that can be used for his relief will vary both in efficiency and in type with the enthusiasm of the doctor whom he consults. The more consultants he sees, the greater will be his conviction that essential vascular hypertension is as yet neither understood nor properly treated.

Aneurysms of the carotid circulation have come in for considerable attention during the past year. Dandy's⁶⁰ report of 3 intracranial cases that were successfully closed by trapping the aneurysm between a ligature of the internal carotid artery in the neck and a second ligature applied to the same vessel intracranially and distal to the aneurysm,

brought to light a number of other cases that have been successfully treated. Furthermore, the fact has been emphasized that a worth while series of cures have resulted from simple closure of the carotid artery in the neck. This however, should not be attempted unless sufficient pre-operative compression of the artery is carried out and unless the operator is certain of his diagnosis. Singleton⁶¹ has written an interesting paper on the arteriovenous type of intracranial aneurysm. His suggested use of sclerosing solutions in the dilated ophthalmic veins is, to say the least, stimulating. Robertson⁶² introduces a note of conservatism in the discussion, and emphasizes the need of preoperative preparation, as well as the successes that have followed the use of non-operative therapy in the past. In general it may be said that intermittent occlusion of the carotid artery in the neck should be practiced before any permanent closure is undertaken. This should be continued until occlusion can be maintained without symptoms for thirty minutes at a time.

All traumatic carotid and cavernous sinus aneurysms should be treated by ligation of the common carotid, to be followed by ligation of the internal carotid in the neck on the side of the aneurysm. Ligation of the ipsilateral and contralateral external carotids can be done before or after intracranial closure of the involved internal carotid and possibly, as Grant⁶³ suggests, intraorbital ligation of the ophthalmic veins in addition. Other types of aneurysm must still be dealt with as individual problems, and with the risks and benefits of therapy assessed separately for each patient.

PAIN

General

Within the last two or three years the injection of cobra venom has come into some use as a method of treating pain that cannot be prevented by other means. Its effectiveness seems to be unpredictable, and there has been need for a greater knowledge of how to use it. Rutherford⁶⁴ offers helpful suggestions along this line. In a carefully controlled series of 17 cases, 46 per cent of the patients were completely and 88 per cent were half relieved of their pain. Rutherford notes that if there is a favorable response it begins on the third or fourth day, and is complete by the sixth or seventh day after the injections are started. No increase in relief can be expected with an increase in dosage. In those relieved maintenance of relief was usually possible with an ampule every other day. The only objection to the use of this substance, so far as I have been able to determine, is the unpredictability of its effect and the expense.

Pitts and Browder⁶⁵ add further evidence relative to the efficiency of spinal subarachnoid alcohol injections for the relief of pain in properly selected cases. If possible, the injection should be so made as not to bathe the sacral roots. Care should always be taken to avoid injecting too large a quantity at any one time. The possibility of causing permanent dysfunction of the bladder and lower bowel, no matter how perfect the technic, should never be forgotten, and appropriate warning should be given the patient beforehand. Even at its worst, the procedure is a distinct aid to the therapeutic measures available for dealing with intractable pain.

Back Pain

Papers about back pain still deal almost exclusively with ruptured intervertebral disks and their protruded nuclei. Fincher,⁶⁶ under the general heading of low-back and sciatic pain reports his attempts to substitute air for Lipiodol in outlining the defect made by the protruded nucleus. In the last analysis, no more can be said today for the substitution of air for Lipiodol in the diagnostic study of these cases than this: it may be tried, but the resultant diagnoses have a very high percentage of error. A better paper that discusses the intraspinal causes of back pain is that by Bradford and Spurling.⁶⁷ They report on 60 cases which include examples of herniated nucleus and thickened ligamentum flavum. The cases have been well studied, and the data on them are unusually complete. Perhaps the best point that these writers make is the importance of studying the distribution of the Lipiodol in the axillary pouches so characteristic of the points of exit of the cauda equina. Preoperative recognition of lateral protrusions of the loose cartilage is possible by this means—a vital point in relation to diagnosis, and to operative technic as well. It cannot be doubted that the time has now arrived for surgeons to become definitely conservative in making the diagnoses of extruded nucleus pulposus and thickening of the ligamentum flavum if they do not wish to undo all the good that has been accomplished to date in dealing with cases of intractable sciatic and low-back pain. The diagnosis of herniation of the nucleus should never be made without symptoms that can be ascribed to irritation or compression of one spinal root, and at least a demonstration by Lipiodol of a characteristic defect at the proper point or an increased cerebrospinal fluid protein, preferably both. Operative interference should not be undertaken by the general or orthopedic surgeon. This operation except for any associated fusion, is a neurosurgical one and should be exclusively carried out by men qualified

in that line. Already much harm has been produced by inadequate and incorrect diagnoses and by the damage done by inept and ignorant operators. The diagnosis of significant thickening of the ligamentum flavum is even more difficult, and even less convincing at operation. It is significant that discussion of its presence has almost disappeared from the surgical literature during the past year. The profession must sedulously avoid making of these conditions, as was done in the past with "sacro-iliac strain," another diagnostic wastebasket.

Pain in the Face

Studies of facial pain during the past year have been chiefly concerned with fifth-nerve neuralgia. The usual crackpot types of suggestion, such as using typhoid vaccine as a therapeutic measure, have been made. A certain persistence in the belief in the efficiency of vitamin feeding as a treatment for tic is also still manifest. However, those who believe in the latter's effect conveniently forget the remissive characteristics of the disease, and the frequent difficulty encountered in differentiating true tic and other facial neuralgias. An increasing individual experience corrects these errors sooner or later. The most significant work was that done by Sjöqvist.⁶⁸ Nothing more fundamental or of greater importance along this line has come out since the original work of Frazier and Spiller. Sjöqvist has been able to work out the pathway of the pain fibers as distinct from those carrying other forms of sensation as they pass through the posterior root of the fifth cranial nerve and into the medulla. As a significant piece of practical neurophysiology, this work cannot be overestimated. As a practical aid by way of a new operation for the relief of trigeminal neuralgia, it still leaves much to be desired. Even in Sjöqvist's hands, the results have not been entirely favorable, and the complications have been rather frequent and severe. Rowbotham,⁶⁹ to be sure, reports favorable results in 2 cases, but this number cannot be considered enough to offset the deficiencies found in Sjöqvist's series of 9. Hyndman⁷⁰ adds another uninteresting chapter to the discussion as to whether the temporal or cerebellar route is the better one to use in extramedullary section of the sensory root of the fifth nerve. The article redeems itself, however, because in it is described a new guillotine knife, which has every appearance of becoming a useful addition to the neurosurgical armamentarium. The perennial difficulty of differentiating true trigeminal neuralgia and the other facial neuralgias is further complicated by the description of a new syndrome of vascular headache and its treatment by histamine. Horton, MacLean and Craig⁷¹ report on 84 pa-

tients who, in the fourth or fifth decade of life, had causeless headaches not of the migraine type. The headaches were accompanied by a constant, excruciating, burning, boring type of pain which was limited to one side of the head and involved the eye, the temple, the neck and often the face. There were no trigger zones. There was frequently marked tenderness on pressure over the branches of the external and common carotid arteries. The attack appeared and disappeared suddenly, and remissions and exacerbations occurred. A vasodilatation on the same side of the head as the pain was invariably coincident with the onset of the pain. Sixty-five patients obtained definite and permanent relief for from two weeks to eighteen months following the subcutaneous injection of 0.05 mg of histamine twice daily for two days. This dose was increased on the third and fourth days to 0.066 mg twice and on the fifth day to 0.1 mg twice. This last dose was continued twice a day for two or three weeks. Surgical intervention is not warranted.

DIAGNOSIS

So many neurosurgical diagnostic procedures used today depend on the introduction into the body of radio-active or radio-visible substances that a knowledge of their dangers and limitations is essential to the surgeon. The use of Thorotrast, while not so indiscriminate as in the past, is still a recognized neurosurgical diagnostic procedure. Jacobson and Rosenbaum⁷² report the postmortem findings and the results of their study of the radio-activity of the tissues taken from a patient who died five years after the use of Thorotrast. In the light of their investigation it cannot be seriously contended that even the diagnostic use of the radio-active substance is harmless. Carrillo,⁷³ in a book on iodoventriculography as applied to posterior fossa tumors, takes what must be considered an extreme view of the necessity for the diagnostic use of radio-active and radio-visible substances. Even though the work is based on 550 cases, I can see no justification for his enthusiasm. Modern tumor neurosurgery recognizes that the type of surgery applicable to the individual neoplasm depends as much on the determination of its cellular make-up as it does on its location. Operative exploration is indispensable in order to determine the former, and will necessarily accomplish the latter without the introduction into the ventricular system of unreclaimable foreign substances. The same criticism applies to the work done by Fischer⁷⁴ in his attempts to make a pre-operative histological classification of cerebral tumors by angiography. It cannot be emphasized too strongly that this process is dangerous, and is justifiable only in very exceptional cases.

With the widespread popularity of the extruded nucleus pulposus as a possible cause of any type of pain in the back and legs, the intrathecal injection of Lipiodol has reached alarming proportions. This is the truer because a knowledge of its late effects on cauda equina, meninges, cord and roots has been conspicuous by its absence. I have had a case in which the aqueduct of Sylvius was blocked after diagnostic intraventricular injection of Lipiodol, and an otherwise normal brain was transformed into one with a slowly advancing hydrocephalus, as the result of the attending doctor's use of his imagination rather than his knowledge. Brown and Carr¹⁶ have contributed a valuable paper on this subject. They review the literature and report one completely worked up case. They conclude that "the use of any substance which may produce such changes cannot be regarded as entirely harmless and its indiscriminate use should not be encouraged."

The recent substitution of 95 to 98 per cent oxygen for air in ventriculograms and encephalograms may possibly be of some use in promoting the comfort of the patient immediately after these procedures. Impartial observers do not agree on this point. All agree, however, that the absorption of oxygen from the ventricles and subarachnoid space is so much faster than that of air that without perfect and immediate roentgenoscopy the final films of a given series of x-ray exposures may be so poor as to be unreadable. Congdon and Burgess¹⁷ fail to emphasize this point in their paper on the use of oxygen in the treatment of abdominal distention and other conditions.

The early recognition of the presence of surgical shock and its differentiation from hemorrhage are of great importance. Moon¹⁸ points out why this is so, mentions the weakness of previous differential diagnostic methods, and offers a simple and an apparently reliable test for such recognition. He reaffirms what many surgeons have stated previously, that arterial blood pressure is not an accurate criterion of the presence of shock. He further states—and others have had the same experience since the publication of his article—"The presence of hemoconcentration is the earliest clinical sign of shock. It is easily detected, is regularly present before other signs appear, and results from the same mechanism which causes shock." He affirms that hemoconcentration may be shown by hematocrit readings, an increase in specific gravity, hemoglobin determinations or erythrocyte counts. His experience indicates that the last is more satisfactory as an index than any of the others. Thus, a rise in the red-cell count

from 5,000,000 to 6,000,000 represents a concentration of 20 per cent. This is ominous, and indicates that the mechanism of shock is already in operation. A concentration of 40 per cent is soon followed by other evidence of circulatory disturbance. The importance of this test cannot be overestimated.

Since alcoholism so frequently complicates craniocerebral injuries, a diagnostic procedure that is reasonably accurate has long been needed. Jetter,¹⁹ although primarily interested in determining the presence of legal intoxication, points out the value of ascertaining the concentration of blood alcohol, and mentions its use in diagnosing coma from an unknown cause.

Myelography, the visualization of the cauda equina through an ingenious development of the cystoscopy principle, has been made possible by Pool.²⁰ He was able to make accurate preoperative diagnoses by this method when other means had failed. Unquestionably the field of usefulness of this instrument will and should spread.

ANESTHESIA

Beecher²¹ introduces a note of sanity in estimating the statistical and other data relative to any given anesthetic. Before accepting at their face value claims made for any one anesthetic as being better than others, the surgeon should bear in mind this author's statement about significant figures for computing relative death rates.

The effects of anoxia, according to McClure, Hartman, Schnedorf and Schelling,²² may usually be demonstrated during anesthesia induced by present-day methods. In view of the increasing popularity of the barbiturates, their statement that the use of these chemicals as narcotics tends to produce anoxia of the histotoxic type must be given due weight. Caution must be observed in their use for other reasons also. This latter applies particularly, in my experience, to the present most popular neurosurgical anesthetic, Pentothal Sodium—sodium ethyl (1 methyl butyl) thiobarbituric acid. Injudicious haste in administration and the use of too large doses induce laryngeal spasm with not only anoxia but also an oxemia. Small amounts of ether by inhalation will stop the spasm but prophylaxis is a better way. The makers advise against the use of this drug in prolonged operations, in patients with significant liver damage and in conjunction with the administration of sulfanilamide. Lundy²³ advocates reduction of the strength of the Pentothal Sodium solution to 25 per cent. He is also concerned with the patient's respiratory activity and on that account considers the drug unsuitable for children and believes it necessary at times to re-

sort to positive-pressure administration of oxygen.

Myerson, Loman, Rinkel and Lesses⁸³ investigated the effects of amphetamine (Benzedrine) on Sodium Amytal narcosis. They found that the former was effective in preventing or counteracting the sleep induced by the latter, and that in addition a rapid and prolonged rise in blood pressure was brought about. The surgical application is obvious.

MISCELLANEOUS

Hyndman and Van Epps⁸⁴ have written an interesting paper on the possibility of differential section of the spinothalamic tract. In connection with this they contend that the dentate ligament actually lies more posteriorly than is popularly supposed, and that the spinothalamic tract extends farther forward than is usually stated. Basing their contention on a presumed laminated arrangement of the fibers in the tract, they argue that, by properly locating the section, pain can be abolished in one region of the body without affecting other parts. The conception is stimulating but needs verification.

Of considerable interest to industrial as well as to neurosurgeons is the paper by Weeks and Alexander⁸⁵ on the distribution of the 60-cycle alternating current in the animal body. They found that the current as they studied it passed through the animal body as through a structureless gel. It always chose the shortest path from contact to contact and was not deflected by anatomical landmarks. If the two contacts were the two hind feet, the current never reached the spinal cord. If the contacts were one hindfoot and one forefoot, the current crossed the spinal cord at such an angle as would demarcate the shortest line from one contact to the other. If the current was passed from forefoot to forefoot, the path crossed the cord with the greatest concentration of current at the seventh cervical segment. In no case did the current actually reach either the medulla or the cerebellum. This would appear to offer an experimental demonstration and explanation of the clinical facts that the respiratory paralysis associated with electric shock is correctable in many cases if therapy is applied early, and that spinal-cord lesions may be frequent and permanent under the same circumstances.

Sodium diphenyl hydantoinate (Dilantin) was introduced by Merritt and Putnam⁸⁶ as an adjunct and a possible substitute for older drugs that have already proved their worth in the medical therapy of convulsive seizures. While its effectiveness in the nonsurgical type of epilepsy has been adequately demonstrated, it does not appear to be as effective in controlling seizures that have what

might be called a surgical background. Too much should not be expected of it, therefore, in such cases.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26101

PRESENTATION OF CASE

First Admission A fifty-five-year-old man was admitted to the hospital complaining of tarry stools.

The patient was well until four months before admission when he noticed a slight amount of bright-red blood in one stool, but saw no more blood in subsequent stools. Three months before entry he went to his doctor because of an "all-in feeling." He complained also of fatigue, weakness, dyspnea on exertion and headache. He was told that his hemoglobin was "30," and was sent home with iron tablets to be taken regularly. Tarry stools appeared while taking the drug and persisted after he stopped treatment. X-ray films were taken, and a duodenal ulcer was diagnosed. He was put to bed for some weeks, was placed on a Sippy diet of milk and cream with Ventrex, and showed a marked improvement. Two months before admission he had gained about 28 pounds and his hemoglobin had risen to "75." He caught a bad cold, however, developed an unproductive cough, and was told by another physician that he had "sinusitis." He began to feel poorly again and rested at home. About three weeks before admission his hemoglobin level was "55," and his stools were tarry black, even without iron. Five days before entry he was seen by a member of the staff of this hospital, and referred here for further treatment. At no time had the patient experienced abdominal pain, nausea, vomiting or fullness after meals. There were no fainting spells, sweating or sudden onset of marked pallor.

The patient smoked ten cigarettes a day, and drank three or four glasses of beer daily in the summertime. He denied the use of hard liquors. He further denied any financial, marital, social or psychic upsets or conflicts during the recent past.

Physical examination revealed a pale, fairly well-developed and nourished man, who lay comfortably in bed. There were no positive findings. The heart, lungs and abdomen were normal, and a neurological examination negative. The blood pressure was 120 systolic, 68 diastolic.

The temperature, pulse and respirations were normal.

Examination of the blood revealed a red-cell count of 2,890,000 with 55 per cent hemoglobin, and a white-cell count of 6800 with 67 per cent polymorphonuclears. The stained smear showed "considerable" achromia and anisocytosis, with a rare stippled cell and an increase in the number of platelets. The urine was negative. The stool showed a ++++ guaiac test. A van den Bergh test was "too low to read," and a liver-function test was normal. A blood Hinton test was negative.

Roentgenograms of the colon by barium enema revealed multiple diverticula, and a gastrointestinal series showed that the mucosa of the stomach and duodenum were thickened throughout. In the duodenum there was what appeared to be a small ulcer crater on the posterior wall in the superior margin. Films brought to the hospital by the patient showed a much larger crater in this area.

There was no evidence of ulceration, polyp or tumor by proctoscopy. Special blood studies showed that the mean cell volume was 250 per cent, and the plasma prothrombin 72 per cent of normal. The bleeding time was 3½ minutes, and the clotting time prolonged (6 to 10 minutes).

The patient was placed on a regime of 15 cc. of Cerophyll (the preparation contains vitamin A, B₁, B₂, C, K and the grass-juice factor) three times a day and was given a blood transfusion. A re-examination of the gastrointestinal tract by roentgenography, fourteen days after the first gastrointestinal series, revealed no definite evidence of ulcer, there was practically no deformity of the duodenum. The small bowel was completely examined and showed no evidence of disease. The patient improved slightly, but continued to pass tarry stools. On the twenty-first hospital day an exploratory laparotomy under nitrous oxide, oxygen and ether was performed, using a long right paramedian incision. The entire gastrointestinal tract was examined. The stomach was normal. There was a small hiatus hernia admitting two fingers, the neck was not tight. There was no induration about the duodenum that suggested ulcer. There was no Meckel's diverticulum. There were no palpable polyps in the colon, though several non-inflamed sigmoid diverticula were palpated. The appendix was removed in the usual fashion, and the wound closed in layers. Post-operatively the patient seemed improved, though he continued to pass tarry stools. He was discharged thirteen days after operation on his pre-operative regime, to be followed at home. Before discharge, a gastroscopy revealed a diffuse hemorrhagic process throughout the antrum and body of the stomach. The mucosa appeared pale and

smooth throughout, with small rugae, the margins of which were markedly reddened. There were numerous areas of submucosal hemorrhage and blotchy reddening. It was stated by the operator that the preliminary drainage of the stomach yielded an ounce of very reddish-brown bloody secretion, which apparently contained no free hydrochloric acid, the secretion, however, was so bloody that the test with Topfer's reagent could not be accurately read. The pylorus was not seen due to angulation.

Second Admission (four weeks later) He continued to pass dark stools, but felt fairly well with Cerophyll, a high vitamin, high-caloric diet, parenteral liver injections and rest. One week before admission he ran out of Cerophyll and failed to replenish it. One day before entry the patient suddenly felt weak and nauseated, though without pain, then vomited a large amount of red blood. He was given several transfusions in an outside hospital then referred back to this hospital for further treatment. His physical examination showed a pale, anemic, obviously ill man who was breathing rapidly. The blood pressure was 105 systolic, 80 diastolic, the pulse 94, and the temperature 99.6°F. The hemoglobin was 30 per cent, and the red-cell count 1,660,000. He was transfused, and a jejunostomy performed for feeding purposes. He developed an acute parotitis, which cleared in several days. On the fifteenth hospital day another operation was performed.

DIFFERENTIAL DIAGNOSIS

Dr. MYLES P. BAKER This patient entered the hospital with a story of duodenal ulcer demonstrated by x-ray examination three months before, apparently treated in conservative fashion, with the result that there was a weight gain and a rise in hemoglobin. We do not know how long he was on a Sippy diet or how much in the way of avitaminosis he may have developed. During these three months the bleeding recurred though there was none of the discomfort we associate with peptic ulcer.

The important findings on admission were anemia without thrombocytopenia or purpuric manifestations elsewhere in the skin or mucous membranes, absence of leukocytosis, which is commonly seen in gastrointestinal tract hemorrhage, absence of splenomegaly and leukopenia as with Bantu's disease, absence of elevated blood bilirubin, bromsulfalein retention or esophageal varices, indicating that primary intrahepatic disease was most unlikely as a contributory cause of the melena, evidence by x-ray of a duodenal ulcer in the same

position as that of three months before, but smaller. Perhaps Dr. Hampton will show those films now.

Dr. AUBREY O. HAMPTON Apparently the radiologist was searching very hard for the source of bleeding because the ulcer crater is not very plain. I assume that he called this small lesion at the beginning of the second portion of the duodenum an ulcer, and I think the surgeon would have had some difficulty in finding it even if it were there.

Dr. BAKER The x-ray report spoke of thickened mucous membranes.

Dr. HAMPTON Yes, of the mucosa of the stomach and duodenum. The duodenal mucosa is thick and irregular. That is the reason I have some hesitation in calling the lesion an ulcer crater. Barium could get in between the folds and project beyond the lumen as that appears to do and suggest an ulcer crater which is really not present. The mucosa of the duodenum is certainly abnormal.

Dr. BAKER The x-ray films show no sign of any fixed diaphragmatic hernia, of a gastric polyp or of a tumor mass of the stomach, such as lymphoma, primary carcinoma or even invading carcinoma from the body or the tail of the pancreas, all of which sometimes cause tarry stools.

We have a moderate plasma hypoprothrombinemia of a degree, 20 to 30 per cent below normal, such as has been shown in postoperative cases. It is dependent here, I imagine, primarily on blood loss, possibly to some extent on the development of anoxemia or of a deficiency disease. We have no evidence of a liver disease that might have prevented prothrombin formation, nor is there any known factor to prevent vitamin K absorption in the small intestine—no diarrhea, no hypermotility. There may have been deficiency in vitamin K intake. I think hypoprothrombinemia has been noted in cases here in Dr. John D. Stewart's laboratory in individuals with duodenal ulcer or ulcerative colitis. Throughout postoperative convalescence, bleeding continued.

Gastroscopy revealed submucous hemorrhages, anemia, and small, reddened rugae. This picture seems at variance with the x-ray findings. I can not interpret it because I do not know enough about gastroscopic pictures. Is it a picture of a superficial gastritis? In such a condition I believe massive hemorrhage is rare. Nor does it seem to be representative of what I find described as hypertrophic gastritis of long standing in which massive hemorrhage has been shown to occur.

Dr. EDWARD B. BENEDICT I should call it an acute gastritis with erosion and hemorrhage.

Dr. BAKER There is no evidence of long stand-

ing hypertrophic gastritis in which erosions represent an exacerbation?

DR BENEDICT After all, you can have erosions in superficial, atrophic as well as in hypertrophic gastritis

DR BAKER Four weeks later, after having been on vitamin K for a week, massive hemorrhage occurred. I am in doubt as to the importance of vitamin deficiency. If it is a primary cause of hemorrhage with overlying superficial erosion in the gastric mucous membranes, superficial ulcer formation and demonstrable submucous hemorrhage by gastroscopy, it is a new disease picture to me. Moreover, the plasma prothrombin should be as low as 40 per cent of normal or less before there is much danger of bleeding. As I understand it, vitamin K given to individuals with a level of 70 per cent is merely a preventive measure. Some do not bleed with a prothrombin level as low as 30 per cent.

I therefore lean to a diagnosis of primary ulcerative gastritis of undetermined type, hypertrophic or otherwise, non-malignant in nature, with a secondary vitamin K deficiency, making for a vicious circle of continuous bleeding. For this, I take it, a subtotal gastrectomy was attempted, with jejunostomy to permit of giving a vitamin K and cholic acid mixture and nourishment without interruption.

DR BENEDICT We have here an interesting case where x-ray examination and surgical exploration failed to show anything wrong with the stomach. On looking inside the stomach I found obvious cause of the bleeding, and it was an acute process which was bleeding at the time I looked in. The longer I do these gastroscopic examinations the more I am impressed with the rapidity with which erosions and small ulcers may heal. They will clear up rapidly and fail to show a few days after hemorrhage. I thought we were dealing with an acute hemorrhagic process from gastritis.

DR ARTHUR W ALLEN This patient was x-rayed in his community hospital by Dr. Robert G. Vance, who thought that there was a definite, posterior-wall duodenal ulcer. These films came down to this hospital with the patient, and Dr. Hampton agreed that there was an ulcer. He confirmed the opinion on further examination here, although he stated that the ulcer was not large. In other words we believed that we were dealing with a typical penetrating duodenal ulcer producing a massive hemorrhage. The man was in the borderline age group,—fifty,—but still his arteries were not sclerotic and we thought that he probably would stop bleeding.

The first operation was done after he had recovered from his hemorrhage. His red-cell count

and hemoglobin were within normal limits that time, and we went in expecting to do a subtotal gastrectomy for ulcer in the duodenum. I have never seen an ulcer in the duodenum that had produced hemorrhage that did not leave a scar that could be seen or felt, even though healing had taken place. In this instance I could find anything abnormal in the duodenum. The stomach was perfectly soft and pliable in every part, and the pylorus was patent. The stomach was normal to palpation and inspection. I then believed that we were probably dealing with hemorrhagic gastritis rather than with ulcer, and did not feel justified in subjecting him to gastrectomy. We had the gastroscopy done after operation, not before, and Dr. Benedict confirmed the suspicion that gastritis was present. The patient continued to bleed in spite of as good treatment as we knew how to give him. Dr. Stuart did the prothrombin level and found it somewhat low, so that is why he was given vitamin K preparation. We did not worry about letting him go home. We thought he would be perfectly all right, and would get over the gastritis on a prepared dietary regimen.

We were greatly surprised when his physician called us up and said that the patient had had another massive hemorrhage and that he was afraid he could not get him to the hospital. I transfused him and sent him in by ambulance. The next day we did a jejunostomy in order to nourish him because we realized that unless he continued to get food and vitamins into him he could not possibly recover. He did well again and his red-cell count reached 3,000,000 and hemoglobin 70 per cent in about two weeks. Then suddenly at five o'clock one morning he felt weak and nauseated, and when we came in to see him a little later, he had obviously had another massive hemorrhage, so without any further ado we took him immediately to the operating room and did a subtotal gastric resection for what we supposed was an uncontrollable hypertrophic gastritis. Much to our surprise the specimen showed a very small ulcer on the lesser curvature of the stomach, no more than 3 mm in diameter, so that Dr. Benedict probably could not see it. I am sure that Dr. Hampton never could have seen it by x-ray. It probably was there at the time of the first exploration, but was so small it could not be felt. I did not know it was there until I looked at the specimen after resection, but it led directly into a large branch of the gastric artery, and it was from that source that the massive hemorrhage had come.

PREOPERATIVE DIAGNOSIS

Hypertrophic gastritis

DR. BAKER'S DIAGNOSIS

Chronic hypertrophic gastritis, with superficial ulcerations

ANATOMICAL DIAGNOSES

Gastric ulcer
Chronic gastritis

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY Dr. Allen has explained that this ulcer was a very small one, slightly less than a centimeter in diameter, and it was also a very shallow one. It penetrated the muscularis mucosae into the submucosa, but there was no thickening, scarring or even inflammatory infiltration of the muscularis. That explains why it was impossible to discover it by palpation. There was nothing on the surface of the stomach that would have given any indication of its presence.

It would be interesting if I could say definitely how old the ulcer was, but I do not believe I can. It showed a little fibrosis in its base, so that it was obviously not an entirely acute ulcer. On the other hand, the scarring was all in such superficial layers of the wall that I hardly believe it could have been very chronic. That it had been present two months seems doubtful. We found no scar to suggest that another ulcer had been present and had healed.

DR. ALLEN We included a little segment of duodenum in the resected specimen. There was certainly no ulcer in that.

DR. MALLORY No, we found nothing in it.

DR. MAURICE FREMONT-SMITH Was there a gastritis?

DR. MALLORY Yes, but there can be no question that the ulcer was the source of the hemorrhage because it eroded into an artery, as Dr. Allen has pointed out, as well as into numerous rather large submucosal veins.

DR. F. DENNETTE ADAMS How many proved cases of massive hemorrhage due to gastritis are there?

DR. MALLORY We have had perhaps a half dozen in the hospital in which we believed that we had proved it, at least we found nothing else.

DR. ALLEN I looked up all of them here. I cannot remember the figures, but they have been published.¹ It is definitely one of the less common causes for fatal hemorrhage, but there have been a number of fatal hemorrhages from that cause and nothing else so far as could be shown.

DR. ADAMS Proved at autopsy?

DR. ALLEN Yes

DR. BENEDICT In 1937 I² reported 20 cases, in a two-year period, of mild to severe hemorrhage from gastritis alone.

DR. ADAMS How do you know it was that alone?

DR. BENEDICT From the gastroscopic picture, negative x ray findings and exploration.

DR. WYMAN RICHARDSON Do you classify this case as one of gastritis or peptic ulcer?

DR. MALLORY Primarily, I have to call it ulcer.

DR. RICHARDSON Why do you not call it gastritis and ulcer?

DR. MALLORY It was a real ulcer.

DR. RICHARDSON It was a real gastritis.

DR. MALLORY All cases of ulcer have gastritis along with the ulcer. I have never seen an ulcer not associated with gastritis.

DR. ALLEN This is the only one that penetrated the large vessels that I have seen associated with clinical gastritis. I think that is the difference. I agree that this is a true ulcer.

DR. BAKER Is it not unusual to have this picture by x ray and find other than gastritis? Must there not have been a diffuse gastritis as well as the localized gastric ulcer?

DR. HAMPTON It is possible that there may have been a severe duodenitis as well. That is frequently associated with ulcer. Hemorrhage might be associated with either gastritis or duodenitis.

DR. ALLEN I did not mean to imply that it was an uncontrollable peptic ulcer. There was plenty of gastritis, as there usually is with peptic ulcer.

DR. RICHARDSON It is rare to have ulceration without hydrochloric acid.

DR. MALLORY That was not very adequately tested here.

DR. HAMPTON How often do you think you can find healed gastric ulcer by palpation?

DR. ALLEN I suppose it would depend entirely on how much inflammation there had been and how much scar tissue had formed in the process of healing. I think one can be a little more certain in the duodenum than in the stomach, because the former is a thin walled structure and you can see a small scar or pucker quite well, but in the stomach you may very well overlook one.

DR. BENEDICT Gastroscopically they heal so quickly that you can very often see no trace.

DR. ALLEN I think we should add that he is well and back at work and has not bled since operation.

CASE 26102

PRESENTATION OF CASE

First Admission A forty-five-year-old Russian carpenter was admitted complaining of pain in the chest

The patient had been well until five weeks before entry, when he developed a severe head cold after exposure to cold frosty weather. The symptoms consisted of mucoid nasal discharge, conjunctivitis, puffy face and a slight nonproductive cough. There were slight anorexia and occasional night sweats. The patient continued with his work and a week after the onset began to have moderate burning pain in the lower posterior portion of the left chest, radiating into the left axilla at the level of the nipple. The pains occurred approximately four or five times daily and lasted about fifteen minutes. The discomfort did not interfere with his activity but occasionally woke him at night when he turned over on his right side. Lying on the left side usually relieved the pain but deep inspiration aggravated it. The cough continued, there was slight dyspnea with exertion, and although the pain recurred up to the day of entry, there was no increase in severity or frequency. Three weeks before coming to the hospital the patient first noted dull gnawing epigastric pain, which recurred about once every three days shortly after meals and lasted for about two hours. It was usually relieved by soda, food or gaseous eructations. There was no nausea or vomiting, but the patient lost 37 pounds during the six weeks preceding entry.

Physical examination showed a well-developed, fairly well-nourished man in no acute discomfort. The heart was not enlarged, and there were no murmurs. The blood pressure was 120 systolic, 80 diastolic. Examination of the lungs showed dullness at the right apex anteriorly and posteriorly. In this region there was questionable bronchial breathing with increased tactile fremitus and vocal resonance. In the lower portion of the left axilla there was impaired resonance with diminished breath sounds and tactile fremitus. No rales were heard. There was slight tenderness and voluntary spasm in the right upper abdomen, but no masses were felt.

The temperature was 100.0°F, the pulse 88, and the respirations 22.

Examination of the urine was negative. The blood showed a red-cell count of 4,300,000 with 80 per cent hemoglobin. The white-cell count was 51,250 with 85 per cent polymorphonuclears, 11 per cent lymphocytes, 2 per cent monocytes, 1 per cent eosinophils and 1 per cent basophils. A stool examination was negative. A blood Hinton test

was negative. The nonprotein nitrogen of the blood serum was 22 mg per 100 cc, and the serum protein 5.6 gm. Sputum was scanty and mucoid, and contained no acid-fast bacilli.

X-ray examination of the chest showed a triangular area of homogeneous density in the central portion of the right upper lobe, the density pointing toward the extreme apex of the axilla. The remainder of the lung field was clear, and the heart and mediastinum were negative. Examination of the esophagus, stomach and duodenum showed no evident abnormality.

The patient's condition remained unchanged. His temperature fluctuated between 98.0 and 100.0°F, and the white-cell count rose to 58,000. He was discharged against advice on the eighth hospital day.

Final Admission (eighteen days later) Following discharge the patient felt quite well for about four days. He then developed marked anorexia and frequent emesis of ingested material, and the pain in the left side of the chest recurred. About a week before returning to the hospital, while turning over in bed, he experienced a severe pain in the left axillary region and immediately coughed up a large amount of foul, yellowish, blood streaked material. The odor caused him to vomit at the same time. Subsequently the emesis ceased, but he continued to raise about a cupful of foul sputum daily. The pain in the left chest became constant and increased in severity. Inspiratory movements and cough aggravated the discomfort.

Physical examination showed the patient to be flushed and evidently ill. The signs in the left lower axilla had disappeared, but those at the right apex were unchanged. The edges of the liver and the spleen were both felt directly beneath the costal margin, but the remainder of the examination was essentially as it had been on the previous entry.

The temperature was 99.6°F, the pulse 90, and the respirations 20.

Examination of the blood showed a red-cell count of 5,070,000, with a hemoglobin of 90 per cent. The white-cell count was 116,000, with 93 per cent polymorphonuclears, 2 per cent eosinophils, 1 per cent lymphocytes and 4 per cent monocytes. No immature cells were found, although many band-form neutrophils were noted. The majority of the polymorphonuclears contained toxic granules and many were vacuolated. Examinations of the stools were negative. The blood chlorides were equivalent to 81 cc of N/10 sodium chloride. The nonprotein nitrogen of the blood serum was 46 mg per 100 cc, and the uric acid 9.6 mg.

A lateral x-ray film of the chest showed a well-

circumscribed, slightly lobulated, ovoid area of consolidation within the central portion of the right lung field. No comparison with the previous films was recorded.

The patient's general condition remained unchanged. His temperature fluctuated irregularly up to 103.0°F. Blood cultures were negative. On the third day the patient developed severe pain in the left lower chest, which required morphine for relief. Inspiratory movements increased the discomfort, and diaphragmatic excursion was limited on this side. The cough continued, and the sputum remained quite foul. The white-cell count rose to 135,000, but there was no significant change in the differential formula. He became progressively weaker and died on the twenty-ninth hospital day, fifty-five days after his initial entry.

DIFFERENTIAL DIAGNOSIS

DR. BERNARD M. JACOBSON The history reveals a previously well patient who developed, with an acute onset five weeks before entry, symptoms of infection of both the upper and the lower respiratory tract, which persisted without letup. The presence of anorexia and night sweats is very suggestive of an infectious process. The cause of epigastric pain, recurring about once every three days, is obscure. The loss of 37 pounds during six weeks is impressive, and raises the question of whether we are faced with disease other than acute or subacute infection.

The physical findings at the first entry were those of consolidation in the right upper lobe, and possibly either a small amount of fluid in the left chest or partial atelectasis of the left lower lobe. The striking laboratory finding is the leukocytosis of 51,000, mainly of neutrophils, with no immature forms involved. This fact suggests very strongly an infectious process. X-ray study of the chest confirmed the physical findings in the right upper lobe.

At this point we may pause to speculate. The physical, x-ray and laboratory findings are not pathognomonic of any one disease, but are suggestive of one of a few, namely pneumonia, pulmonary infarct, lung abscess and, finally, neoplasm. Against pneumonia and infarct is the six weeks' duration of the symptoms. By the time of entry, a pneumonia would certainly have been resolved, nor do the symptoms prior to entry suggest pneumonia. An infarct involving almost the entire right upper lobe is very unlikely in the absence of pain in the right chest and of hemoptysis. Lung abscess is not suggested by either a preceding operation in the mouth or throat, by previous unresolved pneumonia or by an infec-

tious process elsewhere in the body. The marked leukocytosis, of course, is compatible with pulmonary suppuration. Finally, could this be a primary bronchiogenic carcinoma? The duration of symptoms is not too short, the loss of 37 pounds is highly suggestive. The leukocytosis is not consistent with neoplasm alone. On the other hand, secondary abscess formation in a neoplasm would be compatible with all the findings. Metastatic nodules in the pleura on the left side might well have caused the burning complained of in the left axilla.

To return to the final admission—the course of the patient was rapidly downhill. The sudden appearance of very foul sputum is suggestive of abscess that ruptured into the right upper bronchus. The only new physical signs are the palpable liver and spleen. The strikingly high leukocytosis, again without immature forms, is rare in infectious diseases, but has been observed. The absence of myelocytes almost certainly rules out leukemia. The fairly low serum chloride is probably due to infection, poor salt intake, loss of salt through emesis, and increased loss of salt through the skin. The elevated serum nonprotein nitrogen in the absence of anything to suggest nephritis is undoubtedly due to impaired renal function dependent on the moderately low blood-chloride level, and the elevated serum uric acid content is adequately explained both by the impaired renal function and by the infectious process.

The terminal course of the patient was marked by increasing evidence of suppuration and of diminishing pulmonary function. The cause of the sudden severe pain in the left lower chest is not clear, for no physical or x-ray findings are recorded at this time. Either pleural metastatic involvement or pneumothorax from rupture of a metastatic lesion into the pleural cavities is a possibility.

My diagnosis is the combination of bronchiogenic carcinoma of the right upper lobe and secondary abscess.

CLINICAL DIAGNOSES

Myeloid leukemia.
Lung abscess.

DR. JACOBSON'S DIAGNOSIS

Bronchiogenic carcinoma of the right upper lobe, with secondary abscess.

ANATOMICAL DIAGNOSES

Carcinoma of lung (right upper lobe bronchus), with metastases to the regional and retroperitoneal lymph nodes, liver, pancreas, adrenal glands and right kidney.
Leukemoid hyperplasia of bone marrow.

Thrombosis of splenic and portal veins
 Splenic infarction, multiple
 Bronchopneumonia, slight, left
 Pulmonary tuberculosis, healed, apical, right
 Pulmonary emphysema, bilateral, apical
 Arteriosclerosis, slight, aortic and coronary
 Operative wounds sternal biopsy

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY Dr Jacobson has made a very much easier job of this differential diagnosis than did the clinicians who had charge of the patient on the ward or the numerous consultants who were asked to express their opinions. I cannot help wondering if two years ago when this patient was in the hospital Dr Jacobson would have tossed off so easily a white count of 135,000. To many who saw the patient at that time the count was regarded as *prima facie* evidence of leukemia, and the palpable liver and spleen seemed to fit the picture. Some consultants wished to interpret the lung findings also as evidence of leukemic infiltration. The laboratory was asked for aid, and shortly before his death a bone-marrow biopsy was performed. We were as much troubled by it as the clinicians had been by the peripheral blood picture. There was an extraordinary hyperplasia of the white-cell series, with complete displacement of all the fat from the marrow, and although red-cell formation was not interfered with, it seemed buried under the enormous number of cells of the myeloid series. In comparison with an ordinary leukemia, however, it was very striking that in the marrow, just as in the peripheral blood, there was no interference with differentiation and the preponderant cell was a fully mature polymorphonuclear. Opinions in the laboratory staff were divided for and against leukemia, but eventually a diagnosis of probable myelogenous leukemia was recorded. Review of the case two years later makes it quite certain, I believe, that we were in error.

The autopsy showed, as Dr Jacobson predicted, a large bronchiogenic carcinoma occupying most of the right upper lobe and evidently arising from the main bronchus to this lobe. There was no abscess, however. Strangely enough the tracheo-bronchial and peribronchial lymph nodes were not involved, but in the anterior mediastinum was a mass of nodes 5 by 4 by 3 cm. There were massive intra-abdominal metastases lying chiefly in the retroperitoneal tissues and completely replacing the right adrenal gland and the body and tail of the pancreas. The latter tumor had invaded the splenic vein and solidly plugged it with a tumor thrombus. This accounted for the great enlargement of the spleen, which weighed 550 gm., though there were a few peritoneal metastases on its surface. A few partially organized fibrinous thrombi were found in the portal vein but did not occlude it. Numerous sections of bone marrow showed a picture identical with that seen in the biopsy specimen. Everywhere there was massive hyperplasia of the white-cell series, without any failure of differentiation. Nowhere in the body was there a trace of leukemic infiltration, the liver, spleen and lymph nodes being all negative in this regard.

In the intervening two years numerous cases have been recorded demonstrating so-called leukemoid states which closely simulate and may easily be mistaken for leukemia. Jackson's¹ recent paper presents the subject with great clarity. It is evident that chronic sepsis, miliary tuberculosis and certain cases of carcinoma may produce such reactions. In addition there are other cases in which no hint of an etiologic factor can be elicited for which the name "agogenous myeloid metaplasia" has been coined.

THE PRACTICE OF MEDICINE BY UNREGISTERED PERSONS

THE Report of the Committee Appointed to Study the Practice of Medicine by Unregistered Persons should be read and re-read carefully by every physician. It was suggested, perhaps too ambitiously, that the committee study the functioning of the Board of Registration in Medicine and, so far as possible, devise means whereby the Board could and would prevent the practice of medicine by unregistered physicians. The report is wisely restricted to the study of the situation, since its correction is outside the committee's province, although it may properly make recommendations.

The situation revealed by the investigation — and the committee has apparently recorded faithfully what it has found — is truly deplorable. There is

found a lack of the funds necessary for the Board of Registration in Medicine to function properly. However, whether the Board does its work well or not, it is in a crucial position with reference to the health of the people and it is a penny wise pound foolish policy to cramp such a board. It is the part of statesmanship to support adequately this important branch of the government, the great value of which is not generally recognized.

The report of the Board, from which quotation is made, indicates that for the year ending November 30, 1938, the expenses were \$8,419.83. It is well known that under the present system of book-keeping of the Commonwealth this does not include salaries of clerks, which item is probably less than an additional \$2500. This gives a total expense of about \$11,000. The receipts for the same year were \$14,353.

These figures do not strike one as remarkable until one notes also that the population of Massachusetts is 4,350,910 and that the number of physicians in practice is estimated at 8000. It does not seem reasonable that in a community of over 4,000,000 persons with 8000 physicians the sum of only \$11,000 is required by the Board of Registration in Medicine to carry out its work properly. The Board cannot adequately do the work that ought to be done, and this is brought out in part by the report, which shows a judicial spirit in spite of making adverse criticism.

Except for eliminating some of the difficulties of the Board, the suggestions offered do not adequately meet the situation. The committee suggests merely the use of "the present dormant law." The real difficulty lies deeper, and for the work set forth by the committee as necessary, even the full income of \$14,353 would not suffice. One part-time investigator would not be enough and more income is needed. The lack of useful files in the office of the Board is noted in the report, but the mere duplication of the alphabetical index in providing a geographical index would be an item of considerable expense.

There is another fact to be noted in connection with the alleged difficulty of the Board in securing appropriations. Budgets are often made up with the expectation that the estimates will be slashed,

and the slashed appropriation is but rarely approved with the idea of doing a good job. Good administration is too often taken to involve the saving of money, instead of the proper handling of the work to be done. Perhaps, in the controversy over appropriations, if the medical profession manifested its interest in attempting to secure proper financial support for the Board, it would be rendering an important public service. It may be said that, under the statute, the responsibility of the Board in the matter of the practice of medicine by unregistered persons has a very limited scope, namely investigation, which the Board can carry out almost not at all, and the reporting of "the same to the proper prosecuting officers," who do the real investigating.

The committee deserves great credit for directing attention to the situation which it has described and for the admirable restraint of its comment. It might be interesting to hear from the Board of Registration in Medicine. In addition, the recommendation of the committee relative to the registration of all members of the Society with their respective town and city clerks should be closely followed.

HARVEY CUSHING'S SEVENTIETH BIRTHDAY PARTY

ON April 8, 1939, there gathered in New Haven, Connecticut, most of the members of the Harvey Cushing Society, a junior group of neurosurgeons, and many friends of Dr. Harvey Cushing to celebrate his seventieth birthday. To record the events of this party a small volume, *Harvey Cushing's Seventieth Birthday Party* (Springfield, Illinois: Charles C. Thomas, 1939), has been issued, which contains speeches given at the dinner and various letters and tributes. Of particular interest are the remarks made by Dr. W. W. Francis, of the Osler Library in Montreal, reviewing his early association with both Osler and Cushing in Baltimore, and the touching comments of Dr. Cushing himself. There are many tributes from friends all over the world and, from old patients, letters sent to Dr. Cushing in grateful recognition of what

he had done to ameliorate their symptoms. Notes of appreciation that have appeared in various medical journals are also appended, as well as "Notes on the Formative Period of a Neurological Surgeon," giving excerpts from his case records at the Massachusetts General Hospital and an estimation of his life as a house-pupil. The book is beautifully printed and contains some fine illustrations including one of the members of the Harvey Cushing Society, one of the dinner gatherings, and plates taken from the case records of the Massachusetts General Hospital. There is also a reproduction of a crayon portrait of Dr. Cushing, done by Mr. Deane Keller, of New Haven, in 1939.

This volume will be welcomed by a large group of friends and associates of the late Dr. Cushing, as well as by many patients whose lives were saved by his efforts. The edition is limited, there being only 150 copies on special rag paper and a somewhat larger number on ordinary paper. The volume is a companion book to *A Bibliography of the Writings of Harvey Cushing* (Springfield, Illinois: Charles C. Thomas, 1939). The latter was prepared on the occasion of Dr. Cushing's seventieth birthday by the Harvey Cushing Society and is already out of print, and one has little doubt but that the present volume will enjoy the same popularity. This in itself will form a fitting tribute to one of America's greatest physicians.

MEDICAL EPONYM

BELL'S PALSY

Bell's palsy and the respiratory nerve of Bell were described by Charles Bell (1774-1842) in a communication read July 12, 1821, by Sir Humphry Davy before the Royal Society of London, entitled "On the Nerves. Giving an account of some experiments on their structure and functions, which lead to a new arrangement of the system." This appears in the *Philosophical Transactions of the Royal Society of London* for that year.

After describing the "respiratory nerve of the face, being that which is called the *portio dura* of the seventh" and detailing his experiments, he says:

We have proofs equal to experiments, that in the human face the actions of the muscles which produce smiling and laughing are a consequence of the influence of this respiratory nerve.

Cases of this partial paralysis must be familiar to

every medical observer. It is very frequent for young people to have what is vulgarly called a blight by which is meant, a slight palsy of the muscles on one side of the face, and which the physician knows is not formidable. Inflammations of glands seated behind the angle of the jaw will sometimes produce this. All such affections of the respiratory nerve will now be more easily detected the patient has a command over the muscles of the face, he can close the lips and the features are duly balanced but the slightest smile is immediately attended with distortion and in laughing and crying the paralysis becomes quite distinct.

The knowledge of the sources of expression teaches us to be more minute observers.

CHANGES IN MEMBERSHIP

Through an oversight, the Committee on Membership failed to include the names of certain fellows for changes in membership in its report to the Council on February 7.

In order to prevent delay the President has authorized me to submit herewith a supplementary list, with recommendations of changes which will be made effective as of February 7. This list will be presented to the Council for confirmation at the meeting on May 21 and will be included in the official minutes of that meeting.

ALEXANDER S BEGG, M.D., *Secretary*

* * *

SUPPLEMENTARY REPORT OF COMMITTEE ON MEMBERSHIP

The committee recommends.

1. That the following named fifteen fellows be allowed to retire as of December 31 1939 under the provisions of Chapter I, Section 5 of the by-laws

Cause, Georges E., Lowell, with remission of dues for 1938 and 1939
Hannan, David E., York Village, Maine
Hart, Joseph S., Burlingame, California
Hopkins, William T., Lynn
Howe, W. Lewis, Everett
Loughton Florence M., New York City
Learoyd Charles B., Danvers
McCarthy Thomas H., Brockton with remission of dues for 1937, 1938 and 1939
Newhall, Avery L., West Lynn
Outhouse, John S., Shelburne Falls
Pierce, Appleton H., Coatesville, Pennsylvania
Reddy Joseph W., South Boston
Richardson, Oscar, Lakeville
Stone, Frank E., Lynn
Young, Anna R., Waltham

2. That the following named seven fellows be allowed to resign as of December 31 1939 under the provisions of Chapter I Section 7 of the by-laws

Crosbie, Arthur H., Boston
Donley Dorothy E., Columbus, Ohio

Hoffman, Doris, Wolcottville, Indiana
Leith Richard B., St. Petersburg Florida
Nance William K., Wolcottville, Indiana
Philbrick, Maurice S., Skowhegan Maine, with remission of dues for 1939
Whittemore, Wyman Boston

3. That the dues of the following named six fellows be remitted under the provisions of Chapter I Section 6 of the by-laws

Bailey Florence, Lawrence, 1938 and 1939
Coynce, John A. Brookline, 1937 1938 and 1939
Danforth, Mary, China 1937, 1938 and 1939
Kramer Florence R., Lynn 1937 1938 and 1939
Ruston Warren D., Rockport, 1937, 1938 and 1939
Young Ralph R. Jamaica Plain, 1937, 1938 and 1939

4. That the following named two fellows be deprived of the privileges of fellowship under the provisions of Chapter I, Section 8 Clause b of the by-laws

Feigenbaum, Jacob Montreal
Freeman, Norman E. Philadelphia Pennsylvania

5. That the following named fellow be allowed to change his membership from one district society to another without change of legal residence, under the provisions of Chapter III Section 3 of the by-laws

From Middlesex South to Norfolk
Applebaum Jacob Newton

FATAL INTRAPARTUM UTERINE SEPSIS

Mrs. C., a forty-seven year-old para VII, at term, entered the hospital on February 18, 1936, with ruptured membranes, she was not in labor.

The family history was essentially negative, but the patient's husband was tuberculous. The patient gave a history of scarlet fever and an appendectomy. She had had six full-term pregnancies, the last seven years previously. The first and fifth had been terminated instrumentally. The puerperiums had been uneventful. Catamenia began at fourteen, were regular and normal in duration. The last period was May 5 1935, making the estimated date of confinement February 12. The present pregnancy had been uneventful except for false labor at eight months, for which she had been admitted to the hospital and kept under observation for five days.

Examination on entry showed a well-developed and nourished woman. The temperature was 99.0°F., the pulse 94, and the respirations 24. The heart was not enlarged, the sounds were clear and

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

and the slashed appropriation is but rarely approved with the idea of doing a good job. Good administration is too often taken to involve the saving of money, instead of the proper handling of the work to be done. Perhaps, in the controversy over appropriations, if the medical profession manifested its interest in attempting to secure proper financial support for the Board, it would be rendering an important public service. It may be said that, under the statute, the responsibility of the Board in the matter of the practice of medicine by unregistered persons has a very limited scope, namely investigation, which the Board can carry out almost not at all, and the reporting of "the same to the proper prosecuting officers," who do the real investigating.

The committee deserves great credit for directing attention to the situation which it has described and for the admirable restraint of its comment. It might be interesting to hear from the Board of Registration in Medicine. In addition, the recommendation of the committee relative to the registration of all members of the Society with their respective town and city clerks should be closely followed.

HARVEY CUSHING'S SEVENTIETH BIRTHDAY PARTY

DEATH

HAYES—ALBERT E. HAYES, M.D., of Edgewood Rhode Island, died recently. He was in his seventy-fourth year.

Dr Hayes received his degree from the Harvard Medical School in 1898. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

CORRESPONDENCE

MEDICAL AND SURGICAL ASSOCIATES

To the Editor. Medical and Surgical Associates in developing means of providing medical care to members of Health Service, Inc. have from the start aimed toward a plan which would assure a good quality of care, adequate remuneration of associated physicians, and as little disruption of existing practice as possible. Their communication in the *Journal* of December 7 stressed this desire and called attention to certain considerations that would occasion some adjustment of individualistic medical practice under the service. Quite naturally, however, some of the subsequent discussion suggests a misunderstanding of the aims.

It should be clear that desirable conservatism in the introduction of any such service and imperative economic stability prescribe careful organization of the subscribing members and limitation of physicians rendering service under the plan to at least those interested in its success. Any service not controlled in these respects might well jeopardize medical standards and the income of physicians throughout the Commonwealth. It could justly be attacked as being the first step toward ill-controlled state medicine.

Medical and Surgical Associates hope to open this plan to as many physicians as is practical and consistent with conservative principles. The medical care offered to the subscribers to Health Service, Inc., is organized on the basis of having an internist or pediatrician, who has become an "associated physician" available to each subscriber or dependent who will care for that subscriber or dependent in the home, office or hospital and also of having specialists of all types available for consultation. As subscribing members and the demand for medical care increase, Medical and Surgical Associates would like to refer members to practitioners or pediatricians who are interested and who reside in areas where there are a sufficient number of subscribers. In order not to disrupt any more than necessary the relation between family practitioner and specialist, the practitioner may call in as a specialist anyone certified by the appropriate National Board who is willing to join Medical and Surgical Associates as an "associated physician" in a consulting capacity.

HUGH CABOT M.D., Secretary
Medical and Surgical Associates.

SECOND CALL FOR THE PHARMACOPOEIAL CONVENTION

To the Editor. In compliance with the provisions of the constitution and by laws of the United States Pharmacopoeial Convention I hereby issue this second call to the several bodies entitled under the constitution to representation therein to appoint three delegates and three alternates to the decennial meeting of the Convention for the

Revision of the *Pharmacopoeia of the United States of America*, which is to meet in Washington, District of Columbia, on May 14, 1940

WALTER A. BASTEDO, M.D., *President*,
United States Pharmacopoeial Convention.

N B In order that the records may be brought up to date and checked, that card files may be prepared and that the other functions of the Committee on Credentials may be performed, it is desirable that the credentials of all delegates appointed to attend this decennial meeting shall be in the hands of the secretary, Mr L. E. Warren, 2 Raymond Street, Chevy Chase, Maryland, not later than March 15, 1940

FINNISH RELIEF FUND

To the Editor The Finnish Relief Fund, Inc., is sponsored by Mr Herbert Hoover. It is approved by the Finnish Minister in Washington, His Excellency Hjalmar Procope. It has the main purpose of accepting for the Finnish people and transmitting to Finland any funds contributed for this great cause by the American people. Contributions, unless specifically intended to be used for war material, will be used for food and clothing for the Finnish civilian population, many of whom are suddenly made homeless by having their houses irreparably demolished by the incendiary bombs from Russian aeroplanes.

Members of the American Medical Association are the only doctors who will be asked to contribute through this fund. It is hoped the profession will respond as generously as possible. It is further hoped that every doctor will make some contribution, and no matter how small it may be, it will be gratefully accepted. We believe the profession should have one hundred per cent of its members become contributors to this most worthy cause.

No money is deducted for expenses from any contribution made through this fund, and every dollar donated arrives in Finland worth one hundred cents. No salaries are paid and no financial remunerations are made to officers on duty with the Finnish Relief Fund. Expert auditors make a daily checkup of the donations acquired and chart the results.

The national chairman of the Medical Division of the professional groups of the Finnish Relief Fund, Inc., is Dr John Frederick Erdmann, of New York. A director (chairman) for the Medical Division has been or will be appointed from each state, who will try to get in touch with every member of the American Medical Association of that state by such method as he deems best.

All checks should be made payable to the Finnish Relief Fund, Inc., and sent to the Medical Division, Finnish Relief Fund, Inc., 420 Lexington Avenue, New York, N. Y.

KERWIN W. KINARD, *Director*,
Medical Division, Finnish Relief Fund, Inc.

420 Lexington Avenue,
New York City

NOTICES

REMOVAL

FRED C. GUNTER, M.D., announces the removal of his office to 1101 Beacon Street, Brookline.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, March 13,

from 2 to 4 p.m. Drs Elliott C. Cutler and Soma Weiss will speak on "Abdominal Pain."

Physicians and students are cordially invited to attend.

BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday, March 13, at 12 o'clock noon, in the Pathological Amphitheater.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, March 12, in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance) at 8:15 p.m. Dr Soma Weiss will preside.

PROGRAM

Presentation of cases

The Chemistry of Vitamin K Professor Louis F. Fieser

The Therapy of Vitamin K Dr Arnold Seligman

Medical students and physicians are cordially invited to attend.

SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, March 19, at 12 o'clock noon. Dr Herrman Blumgart will speak on "The Clinical Significance of the Collateral Circulation in Patients with Angina Pectoris."

Physicians are cordially invited to attend.

MASSACHUSETTS ITALIAN MEDICAL SOCIETY

The regular meeting of the Massachusetts Italian Medical Society will be held in the Hotel Kenmore, Boston, on Friday evening, March 15, at 9:15. Tel KEN 2770.

PROGRAM

Business

The Bleeding Complications of Pregnancy Dr Roy J. Heffernan.

General discussion

The medical profession is cordially invited to attend.

UNITED STATES MARINE HOSPITAL

The staff meeting of the United States Marine Hospital, Chelsea, will be held at "The Hut," on Friday afternoon, March 15, at 4:00. Dr George C. Shattuck will speak, his subject being "The Causation of Heat Effects with Special Reference to Sunstroke and Heat Exhaustion."

ESSEX SOUTH DISTRICT MEDICAL SOCIETY

There will be a meeting of the Essex South District Medical Society at the Addison Gilbert Hospital, Gloucester, on Wednesday, April 3. A clinic will be held at 5:00 p.m. followed by a dinner at 7:00 p.m. Dr Frederick C. Irving will speak on "The Management of Pre-eclampsia."

MASSACHUSETTS DEPARTMENT OF CIVIL SERVICE AND REGISTRATION

SCHOOL PHYSICIAN, SCHOOL DEPARTMENT NORTHAMPTON

Director of State Civil Service, Ulysses J. Lupien has recently announced that a competitive examination is to be held on April 10 in order to find eligibles for appointment to the position of School Physician, School Department, Northampton. The salary is \$250 a year.

The entrance requirements are as follows: applicants must be registered physicians under the State Board of Registration in Medicine. The last date for filing applications is Saturday April 6 at 12 o'clock noon.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY MARCH 10

SATURDAY MARCH 10

- 4 p. m. Health in Middle Age. Dr. William B. Breed. Free public lecture. Harvard Medical School, amphitheater of Building D.
- 4 p. m. New Drugs for the Treatment of Infectious Diseases. Dr. W. Richard Ormer. Illustrated, public health lecture. Fulkner Hospital Auditorium.

SUNDAY MARCH 11

- 9-10 a. m. Review of Recent Cancer Literature. Dr. W. M. Sheldon. Joseph H. Pratt Diagnostic Hospital.
- 8-11 p. m. Topographic Recordings of Uterine Motility. D. Douglas P. Murphy. Journal Club, Boston Lying-in Hospital.
- 8-11 p. m. Harvard Medical Society. Peter Bent Brigham Hospital (Shattuck Street entrance).

MONDAY MARCH 12

- 9-10 a. m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
- 12 m. Monthly clinicopathological conference. Boston City Hospital.
- 4 p. m. Abdominal Pain. Drs. Elliott C. Cutler and Soma Weiss. Peter Bent Brigham Hospital.

TUESDAY MARCH 13

- 9-10 a. m. The Relation of Cancer of the Stomach to Pernicious Anemia. Dr. Thomas Fujiwara. Joseph H. Pratt Diagnostic Hospital.

WEDNESDAY MARCH 14

- 9-10 a. m. Endocrinology. Dr. Fuller Albright. Joseph H. Pratt Diagnostic Hospital.
- 10-11 p. m. Massachusetts Italian Medical Society. Hotel Waverly.

THURSDAY MARCH 15

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

FRIDAY MARCH 16

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

SATURDAY MARCH 17

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

SUNDAY MARCH 18

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

MONDAY MARCH 19

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

TUESDAY MARCH 20

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

WEDNESDAY MARCH 21

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

THURSDAY MARCH 22

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

FRIDAY MARCH 23

- 9-10 a. m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

DISTRICT MEDICAL SOCIETIES

ESSEX SOUTH

- April 3 — Page 422.
- May 8 — Annual meeting. Salem Country Club, Peabody.

FRANKLIN

- March 12 — Franklin County Hospital, Greenfield.
- May 14 — Franklin County Hospital, Greenfield.

HAMPSHIRE

- March 13.
- May 8.
- Meetings are held at 11:30 a.m. at the Cooley Dickinson Hospital, Northampton.

MIDDLESEX EAST

- March 20.
- May 15.
- Meetings are held at 12:15 p.m. at the Unicorn Country Club, Stoughton.

MIDDLESEX NORTH

- April 24.
- May 31.
- October 30.

NORFOLK SOUTH

- April 4.
- May 2.
- All meetings, with the exception of one which is usually held at the Quincy City Hospital, are held at the Norfolk County Hospital in South Braintree, at 12 o'clock noon.

PLYMOUTH

- March 21 — Goddard Hospital, Brockton.
- April 18 — State Farm.
- May 16 — Lakeview Sanatorium, Lakeville.

SUFFOLK

- March 27 — Scientific meeting. Symposium on Ulcerative Colitis and Diarrhea. Under the direction of Dr. Chester M. Jones.
- April 24 — Annual meeting in conjunction with the Boston Medical Library. Election of officers. Program and speakers to be announced later.
- May 2 — Convener's meeting. Page 244 issue of February 8.

WORCESTER

- March 13 — Worcester Memorial Hospital.
- April 10 — Worcester Hahnemann Hospital.
- May 8 — Worcester Country Club.
- Each meeting begins with dinner at 6:30 p.m. and is followed by a business and scientific meeting.

BOOKS RECEIVED FOR REVIEW

- American College of Surgeons 1940-1941 Year Book*. 1077 pp. Chicago: American College of Surgeons, 1940.

BOOK REVIEWS

Infections of the Hand Lionel R. Fifield Second edition by Patrick Clarkson. 167 pp New York Paul B Hoeber, Inc., 1939 \$3 25

The first edition of this manual was written by Lionel R. Fifield, demonstrator of anatomy at the London Hospital, and appeared in 1926 This second edition has been rewritten by Patrick Clarkson, demonstrator of anatomy at Guy's Hospital Medical School A knowledge of the structure of the upper extremity is of prime importance in the treatment of hand infections, and this work prepared by practicing surgeons, both of whom are teachers of anatomy, is a sound and practical guide for practitioners The 57 illustrations (including 8 plates, 2 in color) have been well chosen to supplement the concise text

A diagram showing iniquitous incisions and the accompanying explanation merit thoughtful study Sloughing of tendons results from impairment of their blood supply, but the catastrophe is not inevitable Early decompression is, of course, vital The surgeon, however, may jeopardize the blood supply of tendons by improperly placed incisions, improper drainage material and the incorrect use of drains These points are noted in the book but could be stressed to great advantage The single paragraph on human bites is inadequate

Chapter XII covers the prognosis of infections in various situations In certain types the authors state the outcome which may be expected by the average operator The reviewer believes that, if the practitioner carefully observes all the instructions set forth in the preceding pages, his incidence of satisfactory results in early cases will be much higher This book is a splendid exposition of the subject.

Physiology in Health and Disease Carl J Wiggers Third edition 1144 pp Philadelphia Lea & Febiger, 1939 \$9 50

Modern physiology makes an effort to integrate most of the medical sciences in order to express the dynamics of living processes, whether they be normal or pathological In the strictest sense it is no longer a specialized science shared by an isolated group of investigators but rather belongs to the entire medical world Unconsciously we have all become physiologists in the broadest meaning of this term In the seventeenth century the new physiology based on anatomy was called by Garrison *anatomia animata* In recent years even the most cut and dried aspects of medicine have become a *medicina animata* Our outlook has changed a bit as we look on most medical problems in the light of function Because of the great role played by physiology the importance of our general source book on this subject becomes at once important

The third edition of Professor Wiggers' *Physiology in Health and Disease* deserves unquestioned praise. It is a

beautifully arranged book, and all the facts are crystallized in such a way that they bear direct relation to each other The experimental work presented is well supported by accurate references, and a listing of monographs and reviews follows each chapter About a third of the volume has been rewritten There has been a blending of the new material with the old without increasing the size of the text to bulky proportions This has been accomplished by the rephrasing of statements and by the judicious pruning of less important or obsolete material Over 1400 new references have been added.

In this edition the author has expanded on subjects having current interest, such as acclimatization, action potentials, cerebellar function, chemoreceptors and pressor receptors, chest pain, degeneration reactions in muscles, dynamics of hypertension, electrocardiographic chest leads, endocrines, functions of the aorta, functional renal pathology, heat elimination, humoral versus electrical transmission of impulses, methods of measuring cardiac output, prenatal respiration, pulmonary circulation, retinal mechanisms of vision, sensory cortex of the cerebrum, vitamins and phonocardiograms Aside from this new material the book is, of course, replete with basic data in physiology It is recommended to medical students, physicians and all inquirers in the field of physiology, and should be a *vade mecum* of everyone interested in medicine.

Stedman's Practical Medical Dictionary Thomas L. Stedman and Stanley T Garber Fourteenth revised edition. 1303 pp Baltimore William Wood & Co., 1939 \$7 50

Dr Stedman, the originator of this well known medical dictionary, died on May 27, 1938, at the age of eighty-four Until a few days before his death, he was actively engaged on the fourteenth edition, and the work was completed by his nephew, Dr Garber The present edition contains many new words, especially of recently isolated hormones, vitamins and so forth All changes in the *Pharmacopoeia of the United States*, as recorded in the first supplement of the eleventh edition, have been noted, and a copy of the Hippocratic Oath has been added as a frontispiece.

A Textbook of Microbiology Kenneth L Burdon Second edition of *A Textbook of Bacteriology* 638 pp New York The Macmillan Co., 1939 \$2 75

This is a simple and concise teaching manual written by the author for his own purposes in the instruction of nurses and of premedical students. It is comprehensive, clear and well written and admirably fulfills its purpose. It is not, in the reviewer's opinion, adequate for the needs of medical students for whom more critical discussions of recent work and more specific documentation of the literature is desirable. Yet even medical students will find this book an excellent review manual because of its completeness and clear presentation There are no serious omissions, and the reviewer has found no important errors The book—extraordinarily comprehensive for its size—shows evidence of having been written by a competent bacteriologist and is just what its writer intended it to be—a text which takes the "middle course" and is neither too elementary nor too advanced It will not supplement the larger and more advanced texts but is distinctly preferable for almost any type of beginner to a number of the oversimplified, elementary books on the market

SURGERY OF THE STOMACH AND DUODENUM

MEDICAL ASPECTS

CHESTER M. JONES, M.D.†

BOSTON

I HAVE been asked to open this symposium on the surgery of the stomach and duodenum, and shall confine my remarks to the medical aspects of the surgery of ulcer.

In the first place, it will be worth while to define this disease in order to furnish a basis for discussion. A peptic ulcer represents a condition characterized by chronicity and by a tendency to recurrence. Its cause is unknown, and unfortunately this is a disease for which we have no assured cure. I believe that it is of the utmost importance to recognize that the disease is one not to be cured but to be managed. Of course, there is no doubt that gastric and duodenal ulcers at times are cured, but such cases are relatively few, and there is always a tendency to recurrence regardless of the type of treatment. It is essential to stress this fact to the patient. Unless he realizes that he has a disease which tends to recur, the moment he is symptom free he will assume that he is cured and subsequently, in the absence of proper care, will be very likely to have a recurrence.

The causes of recurrence are easily listed and are definite. The first and most obvious group consists of indiscretions in diet, the use of alcohol, excessive smoking and whatever constitutes irregular habits of eating or living. The second cause is infection, and by this I do not mean focal infection. Such infection undoubtedly plays a part in recurrence, but it is of minor significance and treatment by the removal of foci of infection is not as a rule followed by successful results. Focal

infection should be treated on its own merits. I refer rather to intercurrent infection, such as an acute upper-respiratory infection. Recurrences following such infection are probably due to sensitization of the gastric or duodenal mucous membrane, with a subsequent reactivation of the process, by a common cold or similar intercurrent disease. Third, and to my mind of paramount importance, are those factors that can be listed under stress and strain, nervous tension, prolonged emotional disturbances and the like. There is no doubt that the average patient with ulcer has numerous extended periods of stress and strain, that he over reacts to them and that these episodes are frequently the cause of recurrence. Unless we recognize all these factors, not only medical treatment but surgical treatment as well is sure to prove unsatisfactory.

The trend in the treatment of ulcer during the last twenty years is very interesting. About twenty years ago treatment was largely surgical. Since that time there has been a definite shift toward medical therapy not from the point of view of curing the disease, but from the point of view of the management of a chronic recurrent condition. More recently, however there has, I think, been a trend back toward surgery away from indiscriminate medical treatment if you will, and toward well planned surgery in cases with accepted indications for surgical interference. The exact and proper percentage of cases requiring surgical interference is still to be determined but there is no doubt that it should include about 20 per cent of all cases.

What are the criteria for surgical interference from the point of view of the internist? An answer to this question is necessary, inasmuch as those of us who are interested in the practice of internal medicine have frequently the duty of making a decision even before the surgeon sees the patient. We are the ones who ought to make

*The section meeting was held and the following four papers read during the annual meeting of the Massachusetts Medical Society, Worcester, Massachusetts, June 8, 1939.

†Assistant Professor of Medicine, Harvard Medical School; physician, Massachusetts General Hospital.

the decision in favor of operation. One indication for surgery is obviously that of acute perforation, and this is generally accepted. A second is that of complete pyloric obstruction. It is also agreed that hemorrhage, in the broadest sense of the term, is frequently an indication for surgery. A fourth indication, which is much more difficult to define but which is perfectly distinct, may be described as a failure of medical treatment. Two other indications should be mentioned: the finding of a gastroduodenal ulcer, and the finding of a gastric ulcer about the nature of which there is some question. Wherever there is real doubt as to whether or not a gastric lesion is malignant, surgical treatment is the only proper approach.

These are the main indications for surgical interference in the treatment of ulcer. An acute perforation is obviously a surgical emergency, but I should like to mention one or two points about this condition. There is an occasional case in which a diagnosis has not been made until four or five days after perforation has occurred. Under such circumstances, I think that most of my surgical colleagues will agree that Ochsnerization and conservative measures may at times be the proper methods of treatment.

One or two diagnostic points are also of some interest in this connection. A perforated ulcer, whether gastric or duodenal, is frequently associated with pain in the shoulder, and this may be the outstanding symptom. Pain referred to the region of the trapezius, in connection with an acute intra-abdominal emergency, should immediately make one think of a perforation of a viscus, most probably in the stomach or duodenum, with some leakage under the dome of the diaphragm. Another situation not so well recognized is the occurrence of pelvic pain in relation to perforation of a gastric or duodenal ulcer. Occasionally such patients do have acute pelvic pain, frequently leading to a diagnosis of acute salpingitis or acute appendicitis, although a careful but brief history would immediately indicate the fact that the patient has a chronic ulcer. This combination of a typical history of ulcer and an acute episode of pelvic pain should suggest the possibility of a perforated ulcer, with drainage of gastric or duodenal contents into the pelvis and local peritoneal inflammation. Needless pelvic or appendiceal surgery would thus be avoided. When a small perforation is suspected, abdominal plates in the horizontal and vertical positions will frequently demonstrate a gas bubble and give a clue to a diagnosis of ulcer.

As to obstruction, there is no doubt that in this event surgery is indicated, but the question always arises as to whether or not there is complete obstruction. In this connection, certain things should

be mentioned. In the first place, one may have traces of barium in the stomach for as long as twenty-four hours after its administration, without any organic disease of the pylorus being present. Such retention may depend entirely on emotional disturbances, and is not in itself conclusive as evidence of organic disease. The x-ray diagnosis of pyloric obstruction, therefore, should always be carefully checked, and should not be taken alone as an indication for surgical interference.

Rarely one encounters postpyloric obstruction, if such a term may properly be used. This is due at times to disease of the gall bladder and resulting inflammatory reaction around the duodenum, pulling it up toward the gall bladder, with kinking and at times an almost complete obstruction. If suspected, such a diagnosis can occasionally be made prior to operation.

Queer deformities of the duodenum well beyond the pylorus, with partial obstruction, always require an adequate history, with particular reference to biliary colic and adequate cholecystography. When pyloric obstruction is associated with the presence of an acute ulcer in or near the pyloric valve, it is extremely important to treat the ulcer medically for a reasonable period of time, with the patient under close supervision. Frequently one finds that gastric stasis disappears under proper medical management, even though the obstruction at first appears to be complete. Such measures are particularly valuable because of the generally accepted fact that gastroenterostomy, as a rule, is the surgical procedure of choice in the presence of complete pyloric obstruction. When pyloric obstruction is not complete, gastroenterostomy is frequently a failure, and it is therefore absolutely necessary to establish beyond doubt the degree of obstruction before determining the necessity for surgery or the nature of the operation to be employed. With a sufficient degree of stasis, there is no doubt that surgery is indicated.

I must emphasize, however, that in the presence of pyloric obstruction one is often dealing with a poor-risk patient. Obstruction itself naturally results in undernutrition, loss of electrolytes, protein deficiency and the danger of postoperative edema, so that adequate preparation is essential in many of these cases before operative measures are considered. Replacement of electrolytes with normal physiological saline solution and replacement of serum protein by blood transfusion are always advisable, and in some cases jejunostomy may be seriously considered as a proper maneuver, for the purpose of providing adequate nutrition before any gastric surgery is attempted.

Hemorrhage I shall mention only in passing, because it is too large a subject for discussion. Acute

massive hemorrhage is not as a rule an indication for surgery. The risk to patients under forty five years of age is minimal, whereas that of surgical intervention is great. In patients over forty five, the mortality from hemorrhage increases rapidly and there may be an occasional case where surgical interference, if the site of the lesion is known and if the patient is under proper supervision, is indicated. This group of patients, however, is very small, and even here the risk of emergency surgery performed to stop bleeding is so great that it should always be avoided if possible. With in forty-eight hours after massive hemorrhage the decision must be made as to the course to be pursued, and surgical measures, if indicated, should be attempted at no later date.

I may say a word here about transfusions. There is no doubt that they help in the treatment of massive hemorrhages and are a valuable means of combating shock, and if properly given they do not raise the blood pressure. Citrate transfusions given by the direct method, can be used with complete satisfaction. If several transfusions have been given, surgical intervention is probably unwise. I believe that my surgical colleagues will agree that the administration of several transfusions practically precludes surgery, inasmuch as such patients do not stand operation well. Therefore, it is of the utmost importance to come to a decision as to the method of treatment within twenty-four to forty-eight hours after massive hemorrhage has occurred. On the other hand, repeated gross hemorrhages undoubtedly constitute an indication for surgery, but this should be an elective operation with proper preoperative preparation.

The most difficult decision in ulcer therapy is that of advising surgery because of the failure of medical treatment. Such a decision obviously can be made only on the basis of long experience. Patients who have not done well after prolonged medical treatment, because of their failure to follow the prescribed treatment or because of social or economic factors, or because in spite of really adequate medical treatment the ulcer is intractable, deserve surgery. Such surgery should be undertaken with the idea of giving the patient more adequate protection against recurrences, and should therefore be performed only after very thorough consideration. In such cases, however, the most radical surgery is probably the most conservative, and hence the operation should be limited to subtotal resection.

I believe that there is another place for gastroenterostomy in addition to the indication already mentioned,—pyloric obstruction. There are a few patients who do not have such obstruction and who constitute poor surgical risks because of as-

sociated cardiac or pulmonary diseases, and yet have intractable ulcers. These patients are usually if not always in the later decades of life, and the risk of major surgery (subtotal resection) is much greater than that of gastroenterostomy. In this group of cases there is still an occasional one where gastroenterostomy is the operation of choice.

The reasons for the failure of surgery, I think, are three—the unwise choice of the patient, of the type of surgery and of the surgeon. First, one must size up the individual patient—his psychological reactions, his business and social background, the stress and strain to which he is subjected and his ability to carry out orders. If after thorough consideration of these factors it seems certain that the patient will be unable to carry out any reasonable medical regime, a reasonable corollary is that surgery, too, will be ineffective and that recurrences may be encountered. Second selection of the type of surgery needed in the individual case involves the criteria mentioned above in discussing complete or incomplete pyloric obstruction hemorrhage and so forth. Finally in major gastric surgery it is of the highest importance to choose the proper surgeon for such surgery involves a technic calling for extreme skill and wide experience.

* * *

In spite of all the surgical and medical skill available, peptic ulcer is still a chronic recurrent disease in the sense that a cure for it cannot be guaranteed, regardless of the type of treatment. One should never forget that after all the disease may recur, even if an almost complete gastrectomy has been done, and that no matter how radical the surgery, the patient must continue under medical supervision of some sort.

GASTROSCOPIC EXAMINATION*

EDWARD B. BENEDICT, M.D.†

BOSTON

SINCE the advent of the Wolf-Schindler flexible gastroscope,¹ which was first used in this country at the Massachusetts General Hospital six years ago,² our conception of gastric disease has undergone considerable change. We now actually see the inside of the stomach in health and disease and can observe changes in the gastric mucosa which are not demonstrable by any other method of examination. Gastroscopy is a safe procedure, easily performed in the office or outpatient depart-

From the Massachusetts General Hospital.

*Assistant in surgery Harvard Medical School; assistant surgeon, Massachusetts General Hospital.

ment, and well tolerated by most patients. The correct interpretation of gastroscopic findings, however, requires much experience, and the examination should therefore be in the hands of a few well-trained gastroenterologists.

CHRONIC GASTRITIS

By the frequent use of the gastroscope both here and abroad it has been shown that chronic gastritis is the commonest disease of the stomach.³⁻⁵

Chronic gastritis is of great importance to the surgeon for the following reasons: massive hemorrhage may come from gastritis alone⁶; severe gastritis associated with gastric or duodenal ulcer may be an indication for or against operation, depending on the degree and location of the gastritis, and postoperative gastritis is sometimes the cause of serious symptoms and its presence may be an indication for further surgery.

Hemorrhage from Gastritis

In a previous report⁶ the complication of hemorrhage has been emphasized. It may be slight, severe or occasionally fatal. Gastroscopically it is usually possible to demonstrate a red, edematous mucosa, exudate between the folds, submucosal hemorrhages and mucosal erosions, sometimes with active bleeding. Such patients have occasionally in the past been subjected to laparotomy and nothing found. By gastroscopy it is possible to show that the bleeding is coming from a severe gastritis, often involving almost the entire gastric mucosa. Because of the extent of the disease and its generally good response to medical treatment, surgery is usually contraindicated.

CASE 1 S C (M G H No 133540), a 51-year-old man who complained of repeated attacks of weakness and pallor, was referred for gastroscopy. On admission the patient appeared poorly nourished and sallow. The red cell count was 1,800,000, and the hemoglobin 32 per cent. Gastric analysis after administration of histamine showed no free acid. Benzidine tests on the gastric secretion and on the stools were strongly positive.

Gastroscopy was performed on June 9, 1938. Preliminary drainage of the stomach yielded 4 cc. of dark red blood. Because of angulation the pylorus was somewhat difficult to see, but it appeared entirely normal. The antrum and lower part of the body had a diffuse, mottled, red gray appearance. Lying on the greater curvature in the body of the stomach was a large, dark red blood clot of irregular shape. There was a small amount of bright-red blood. Also in this region on the posterior wall in the upper part of the body there was a definite verrucous appearance and superficial erosion. There was no evidence of ulcer or neoplasm. The findings indicated superficial and hypertrophic gastritis with erosion and hemorrhage.

Gastroscopy was repeated on June 30. Preliminary drainage of the stomach yielded 4 cc. of very thick, bloody secretion. The view was again obscured by the presence of blood in the stomach. So far as could be determined, there was no ulcer and no neoplasm. Because of the

presence of blood, however, I did not believe that all parts of the mucosa had been satisfactorily examined, and therefore thought that the patient should still be carefully watched and studied, by both x ray and gastroscopy, for further developments. The mucosa, however, appeared distinctly better. No superficial erosions were visible at this time. There was still evidence of superficial and hypertrophic gastritis. As we have had a number of patients bleed very severely from gastritis alone, it is quite possible to explain this hemorrhage and other symptomatology on such a basis.

In spite of a very careful medical regime, further bleeding occurred, so that readmission was necessary 6 months later. X ray examination on January 3, 1939, showed a normal esophagus. The stomach was high in position, smooth in outline, with good peristalsis, and showed no residue after 6 hours. The rugae appeared thickened. The impression was that of hypertrophic gastritis.

A third gastroscopy was performed on January 19. The

FIGURE 1 Case 1

Severe extensive chronic gastritis with erosions and active hemorrhage. Surgery is contraindicated as the process is too diffuse. X ray treatment was given with benefit.

pylorus was not seen. Peristalsis was normal. The mucosa throughout presented a hemorrhagic appearance, with multiple erosions and blood clots throughout the antrum and body, extending well up to the cardiac orifice. The mucosa throughout was reddened and showed areas of submucosal hemorrhages, as well as hemorrhagic erosions. It appeared very fragile and presented many wart-like excrescences typical of hypertrophic gastritis. The rugae also presented a markedly beaded appearance. The process was very diffuse and severe. The findings were those of a chronic superficial and hypertrophic gastritis, with multiple erosions and hemorrhages.

I advised a trial of x ray treatments in an effort to stop these hemorrhages, with the idea that, if this were unsuccessful, gastric resection might be necessary, though the process was so diffuse that almost a total gastrectomy might be required. Four x ray treatments were given on successive days to the epigastrium, the total dose being 520 r. The bleeding was controlled and the patient gained 15 pounds in weight.

This case represents severe hemorrhage from extensive chronic gastritis (Fig 1). Accurate diagnosis was possible only by gastroscopy. There was definite benefit from x ray treatment. Surgery was not indicated, as the process was too diffuse.

Severe Gastritis with Duodenal Ulcer

Gastritis is frequently seen associated with gastric or duodenal ulcer. A knowledge of the degree and location of the associated gastritis should be one of the important factors to influence the surgeon in deciding for or against operation, and in planning the type of operative procedure. If a diffuse gastritis is present, or severe gastritis of the fundus, probably neither a gastroenterostomy nor a radical operation will be indicated, for the gastritis of the upper part of the stomach will persist and continue to give symptoms. If there is no gastritis, a simple gastroenterostomy or pyloroplasty may be sufficient. If gastritis is localized in the antrum resection may be indicated.

Case 2. S. L. L. (M. G. H. No. 163982) a 25-year-old man, was admitted to the hospital complaining of epigastric pain and vomiting of 7 years duration which had been relieved by diet.

Examination showed slight epigastric tenderness. The red-cell count was 5,000,000 and the hemoglobin 100 per cent. Guaiac tests on vomitus were positive to strongly positive.

X-ray examination on November 28, 1938 showed the esophagus to be normal. The stomach contained a moderate amount of secretion. The rugae were not appreciably thickened. No defects were present in the stomach. The first portion of the duodenum was quite irritable, and it was constantly deformed. In the central portion of the cap about 1 cm. beyond the valve there was a constant crater probably on the posterior wall. At the end of 6 hours the stomach was empty. Some barium from the motor meal lay in the cecum. The findings were those of active duodenal ulcer probably of the posterior wall. Repeat x-ray films on February 20, 1939 showed that the stomach was cascade shaped. The pylorus opened readily and a cap with marked deformity was filled. There was a narrow pouch toward the greater curvature and a large pouch on the lesser curvature. The crater previously described had decreased in size, but was still visible. The findings were those of marked scarring due to duodenal ulcer which was still active. Another examination on March 9 showed the esophagus and stomach as before. The pylorus opened readily filling a cap which if anything was slightly smaller than at the previous examination. The pouches at no time filled to the extent noted at that examination. No ulcer crater could be definitely demonstrated.

The patient's course in the hospital was unsatisfactory. He was uncomfortable and vomiting. Surgery was seriously considered.

Gastroscopy was done on March 17. Preliminary drainage of the stomach yielded 30 cc. of clear slightly greenish material, which contained free hydrochloric acid. Prepyloric contraction was seen but probably not quite down to the pylorus. There was no peristalsis. The mucosa throughout showed increased reddening but otherwise the antrum appeared normal. Throughout the body

and upper part of the stomach the mucosa showed a very marked verrucous appearance with beading of the rugae, particularly on the lesser curvature, posterior wall and greater curvature, with numerous areas of blotchy reddening and three or four erosions about 5 mm. in diameter. There was no active bleeding. I believed that the gastritis in this patient played an important part in his symptomatology. It was so extensive that gastric resection would not remove all of it; moreover there would be the usual postoperative gastritis after resection. On this account, and also because of the gastric acidity and the temperament of this patient, it seemed to me that surgery should be avoided if possible. I believed that the youth of the patient was also against a good surgical

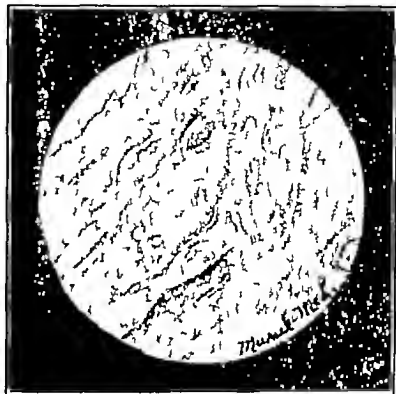

FIGURE 2. Case 2

Severe diffuse gastritis associated with duodenal ulcer. The extent and location of the process were contraindications to surgery. The symptomatology did not clear up with the healing of the ulcer but with the healing of the gastritis (Fig. 3).

result. He had apparently never been very co-operative, but I thought that if the situation were carefully explained to him, and if he were carefully followed in the Gastrointestinal Clinic, he might be brought under fair control medically. I advised complete elimination of tobacco and an absolutely rigid schedule of meals by the clock, with powders if necessary. If the patient could not follow this rigid schedule without operation I did not expect that he would do well after an operation.

Gastroscopy was repeated on April 4. Preliminary drainage was not done. At this examination the mucosa showed very marked improvement. There was only one area on the posterior wall of slightly blotchy reddening and slightly verrucous appearance. Otherwise the mucosa appeared almost normal.

Continuation of medical treatment was advised and on April 16 the patient was discharged home, symptom-free.

In spite of the fact that this patient's ulcer had apparently healed by x ray on March 9, his symptoms persisted and gastroscopy demonstrated the presence of a severe gastritis (Fig. 2). Surgery had been seriously considered, but when the extent and

severity of the gastritis were demonstrated it was decided not to operate. The clinical improvement three weeks later coincided with the improvement in the gastric mucosa shown by gastroscopy (Fig 3). In this case, then, the gastroscopic finding of

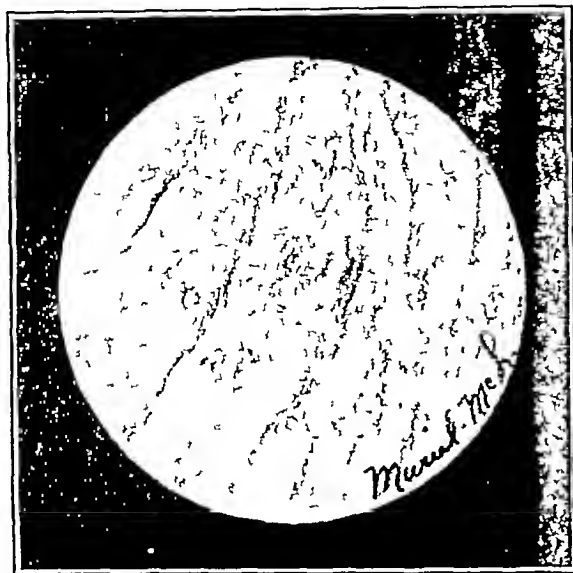

FIGURE 3 Case 2

With the healing of the gastritis, as shown in this illustration, there was an improvement in the symptomatology

a severe generalized gastritis was important in explaining the continued symptomatology after the apparent healing of the ulcer, and in contraindicating surgery.

Postoperative Gastritis

Pathologic changes in the gastric mucosa are not infrequently found in the stomach postoperatively. Sometimes, though not always, postoperative gastritis is the cause of severe symptoms. When it can be shown gastroscopically that the gastritis is localized in the region of the stoma, further surgery may be indicated.

CASE 3 C S H. (P H. No 1312), a 46-year-old man, had had a pylorectomy and posterior gastroenterostomy in 1929 for perforating duodenal ulcer. He entered the hospital complaining of repeated attacks of hematemesis and melena of 3 years' duration, with no evidence of ulcer by repeated x ray examinations.

Physical examination on admission was essentially negative. The red-cell count was 4,000,000 and the hemoglobin was 75 per cent. The clinical impression was that of bleeding from the duodenum.

Gastroscopy was performed on January 19, 1939. Preliminary drainage of the stomach yielded 165 cc. of thick, greenish material. Following this, gastric lavage was done. The patient was very co-operative and a good view was obtained. There was a moderate amount of whitish material clinging to the mucosa, particularly in the antrum, some of which might have been barium, but part of

which was probably the exudate frequently seen in post-operative gastritis. The antrum showed superficial reddening, with areas along the lesser curvature of sub-mucosal punctate hemorrhages. Peristalsis was normal, and appeared to pass well down the antrum to the region where the pylorus should be. It appeared from this and from the x ray studies that very little of the antrum was resected at the time of pylorectomy. The gastroenterostomy stoma was not visualized, as it was apparently closed at the time of this examination and lay behind some folds in the mucosa. The greater curvature and posterior wall in the mid-portion of the body of the stomach showed a markedly verrucous and inflammatory appearance, with reddening of the folds, and two erosions 2 to 3 mm. in diameter. The upper part of the stomach also showed a moderate degree of gastritis, but I believed that most of it was in the region of the stoma. The findings indicated a marked superficial and hypertrophic postoperative gastritis with erosions and hemorrhage.

I thought that a large amount of bleeding could come from this patient's gastritis. From the previous operative note it was impossible to conclude how much duodenum had been resected, but I got the impression that at least part of the first portion was resected and the duodenum infolded. I therefore rather doubted the presence of a duodenal ulcer. I believed that the anatomical setup was functionally poor, as it left a blind pouch which emptied poorly, and which had caused a marked gastritis of the antrum and of the region of the anastomosis. I therefore judged that gastric resection was advisable, with removal at least of all the antrum distal to the stoma, and very likely a higher resection to include the stoma and to give a Polya anastomosis. At that time a further part of the first portion of the duodenum could be resected if necessary.

On January 30 a partial gastrectomy was done. The duodenal stump felt normal, with no induration suggestive of ulcer. There were extraordinarily large vessels over the antrum and the region of the anastomosis. There was no evidence of jejunal ulcer. Two thirds of the stomach was resected, together with the involved portion of the jejunum. The pathological specimen was described as a partially opened, pink, hemorrhagic stomach, with rugae normal in number, consistence and thickness, but flecked everywhere with beefy red spots. The pathological diagnosis was subacute and chronic gastritis.

The patient did well postoperatively, and up to June 5, 1939 had had no further bleeding attacks.

In this case the clinical impression was that the bleeding was coming from the duodenum. Gastroscopy, however, showed a severe chronic gastritis with erosions and hemorrhage (Fig 4), especially in the region of the gastroenterostomy stoma. Partial gastric resection confirmed these findings and showed a normal duodenal stump. The pathological report was subacute and chronic gastritis. The patient has remained well with no further bleeding.

From a consideration of these cases of gastritis it should be emphasized that all patients with unexplained gastrointestinal bleeding should have gastroscopic examination. Hemorrhage from gastritis is not uncommon. It is important to determine the extent and severity of the gastritis and

to follow the healing process by gastroscopy. The usual case with hemorrhage from gastritis will respond to rest and dietary measures with iron, liver and vitamin therapy. Schindler,² however, has reported a case of very severe gastritis treated by heavy x radiation. There were many erosions, but no mention was made of bleeding. One year later a marked atrophic gastritis developed, which Schindler attributed to the x-ray treatment. It is too soon to know the final result in Case 1,

FIGURE 4 Case 3

Severe postoperative gastritis with hemorrhage localized near a gastroenterostomy stoma. Resection was performed with good result.

above. Certainly, as Schindler points out, "x-ray therapy should be used only in the most severe cases."

In Case 2 the persistence of symptoms after apparent healing of the duodenal ulcer is of special interest. The relief of symptoms coincided with the marked improvement in the mucosa shown by gastroscopy.

BENIGN ULCER

The gastroscopist can be of aid to the surgeon in the diagnosis and treatment of gastric ulcer³ in the following ways: gastric ulcers, especially the superficial ulcers which are not seen by any other method of examination, may be seen by gastroscopy; the associated gastritis can best be evaluated by gastroscopy; gastroscopic examination is of assistance in differentiating benign and malignant ulcer, and gastroscopy is of value in following the healing process.

Case 4. A. K. (M. G. H. No. 109873) a 51-year-old woman, entered the hospital complaining of abdominal pain and vomiting, often relieved by food or soda. On

examination she showed epigastric tenderness. The red cell count was 5,500,000. Guaiac tests on the stools were strongly positive.

X-ray examination on February 17 1938 showed a crater 2.5 cm. in diameter on the posterior wall of the stomach just below the cardia with marked surrounding induration. There was marked convergence of the rugae toward the ulcer. The floor of the ulcer contained an irregular filling defect, possibly due to blood clot or to food. The cap did not fill during examination. No stress was laid on its demonstration on account of the preceding hemorrhage. The gross findings were those of a large, benign ulcer in the area described. Re-examination after medical treatment was suggested.

Gastroscopy was performed on February 23. Preliminary drainage yielded 7 cc. of cloudy mucus which contained no free hydrochloric acid. The pylorus was well seen and appeared normal. Peristalsis was rather sluggish. The antrum was normal. There was a verrucous appearance of the anterior wall in the lower part of the body of the stomach with a beaded appearance of the rugae. Above this area on the anterior wall was an irregularly shaped ulcer about 0.5 by 1.0 cm. in diameter, with a clean, white base and very slightly reddened margins. There was no depth to the ulcer and the margins were very sharply outlined. There was no induration in this region. On the posterior wall close to the cardia was a large, very deep ulceration with a fairly smooth grayish-white base, and sharply defined slightly undercut margins. The lesion itself appeared to be circular and from 2 to 3 cm. in diameter. The surrounding mucosa looked normal and not nodular. There was one very large fold running transversely directly from the large posterior wall ulcer to the small anterior wall ulcer. Distal to this fold was a lake of mucus. From this examination I concluded that both ulcers were benign.

X-ray examination was repeated on March 21. The large ulcer had markedly improved. It was thorn-shaped, and measured about 1 cm. across the base and not quite 1 cm. in depth. There was marked convergence of the rugae toward the ulcer. The surrounding swelling involved only about one quarter of the area it had involved on the previous examination. The patient showed improvement with gain in weight, and by x-ray examination on September 26 the ulcer was seen to have further decreased in size, although it was still visible.

Gastroscopy was repeated on October 6. Preliminary drainage of the stomach yielded 15 cc. of thick grayish yellow secretion, which contained free hydrochloric acid. The pylorus was only partially seen through the angulus, but appeared normal, and on the lesser curvature was a grayish-white patch 1 cm. in diameter appearing somewhat like leukoplakia. On the anterior wall in the middle of the body of the stomach was a punched-out ulcer with clear-cut, gray margins and clean, gray base, apparently healing. The rugae seemed to converge toward it, and the ulcer appeared to be about 2 to 3 mm. deep with high folds surrounding it. There was a very marked cobblestone appearance in this region. On the posterior wall near the lesser curvature, fairly high up and about 4 cm. from the cardia, was another elongated ulcer lesion about 2 by 1 cm. in diameter which appeared very similar to the ulcer just described. The cobblestone appearance was also marked in this region and in fact quite generally throughout the body of the stomach with increased redness. The findings indicated an anterior wall and a posterior wall ulcer both of which were probably benign and surrounded by very marked hypertrophic gastritis. In view of the presence of these ulcers for 8 months under

careful treatment, and the marked cobblestone appearance near the ulcers, malignancy could not be excluded. The presence of free acid and the absence of symptoms were somewhat against a diagnosis of carcinoma, but not conclusively. The posterior wall ulcer was so high up that surgery would have been difficult.

A third gastroscopy was done on November 17. Preliminary drainage of the stomach yielded nothing. The examination was confined chiefly to the upper part of the stomach. The ulcer on the anterior wall had completely healed, and that on the posterior wall appeared very shallow and about 0.5 cm. in diameter, with a reddening of the mucosa, convergence of the rugae and a cobble-

stone appearance. The last gastroscopic examination showed complete healing of the ulcer on the anterior wall and marked improvement in the large ulcer on the posterior wall. Gastroscopy also revealed a very marked associated gastritis.

MALIGNANT ULCER

The differential diagnosis between benign and malignant gastric ulcer is often difficult and sometimes impossible. Every means at one's disposal should be employed to make this diagnosis. Gastroscopic examination is a valuable aid in this respect. An ulcer with a clean base and sharply defined margins is probably benign, whereas an ulcer with a dirty base and nodular margins is almost

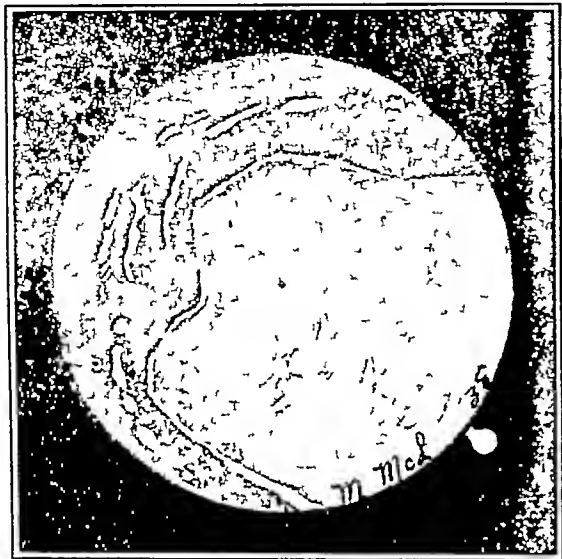

FIGURE 5 Case 4

Large posterior-wall gastric ulcer shown by gastroscopy to have sharp margins and a clean base and to be benign

stone appearance in this region. The findings indicated a very marked improvement since the previous examination. There was no evidence of malignancy.

Re-examination of the stomach by x-ray on December 1 showed the area previously described to have further regressed. There was mere convergence of the rugae, with a small pooling of barium that might have been due to the puckering of a scar. The stomach in this area showed beginning hourglass deformity.

The patient was symptom free until February, 1939, when she developed carcinoma of the cecum, which proved to be inoperable.*

In this case gastroscopy contributed valuable additional information in four respects. It showed the lesion to have sharply defined margins and a clean base, so that malignancy was made to appear very unlikely (Fig 5). A second ulcer, not previously suspected, was demonstrated (Fig 6). The demonstration of multiple ulcers is important in itself, but particularly so when the question of malignancy arises, for multiple malignant ulcers in different parts of the stomach are extremely rare, whereas multiple benign ulcers are not un-

FIGURE 6 Case 4

Small anterior wall gastric ulcer in same patient. This ulcer was demonstrated only by gastroscopic examination

surely malignant. As Schindler³ has pointed out, the presence of the circulating blood in the living tissue is of great help to the gastroscopist.

CASE 5 G E W (M G H. No 132669), a 43-year-old man, was admitted to the hospital complaining of right-sided abdominal pain, with vomiting of 14 months' duration. On examination there was tenderness in the epigastrium. Analysis of the fasting content of the stomach showed 13 units of free hydrochloric acid. One half hour after administration of alcohol and histamine the gastric secretion showed 36 units of free hydrochloric acid.

X-ray examination was done on October 25, 1938. The esophagus showed no evidence of varices. The upper part of the stomach was normal. On the lesser curvature just above the antrum there was an ulcer crater 4 cm. in diameter, which extended into the stomach wall for 2 cm and was surrounded by a marked zone of edema. The stomach below this ulcer and the duodenum showed no evidence of disease. The ulcer seemed grossly benign, but malignancy could not be ruled out.

Gastroscopy was performed on November 10. Preliminary

*At autopsy performed at another hospital the gastric ulcers had apparently healed. There was no evidence of gastric malignancy.

ary drainage of the stomach yielded 4 cc. of slightly bloody secretion which contained free hydrochloric acid. The pylorus and antrum appeared normal. Peristalsis was normal. On the lesser curvature at the angle of the stomach was a large deep ulcer probably 3 cm. in diameter and 1 cm. deep, with slightly nodular margins and a dirty base containing barium and blood clot. The surrounding mucosa was nodular (Fig 7). The gastroscopic appearance, as well as the size of the lesion made me very suspicious of neoplasm and I believed that the patient would have to be explored.

FIGURE 7 Case 5

By showing slightly nodular margins and a dirty base in this lesion gastroscopic examination alone made the correct diagnosis of malignant gastric ulcer

On November 17 subtotal gastric resection was done. The pathological diagnosis was adenocarcinoma. The report in detail ran as follows:

The specimen consists of a subtotally resected stomach measuring 20 by 15 cm., on the lesser curvature of which is an ulcer crater measuring 3.5 by 1 cm. in diameter and 0.8 cm. in depth. This is located 5 cm. from the pylorus. The crater is slightly firm and the mucosa is undermined for 1 mm. The surrounding mucosa shows rather marked gastritis. Microscopic examination shows a broad shallow saucerlike area of peptic ulceration with a fibrinoid membrane and a base of granulation tissue. Just under the edge, at a point where the ulcer slightly undermines the mucous membrane is a small focus, about 5 mm. in diameter of well-differentiated adenocarcinoma. Although it is well circumscribed it shows some degree of invasion of the mucous membrane from below. The balance of the mucous membrane, however, is normal except for evidence of gastritis. No invasion of the blood vessels, lymphatics or perineural invasion can be made out. In view of the small size of the tumor and excellent differentiation the prognosis would seem to be very favorable.

All the clinical evidence to the contrary notwithstanding, the gastroscopic diagnosis of probable malignant gastric ulcer proved to be correct.

CARCINOMA

In a previous report,⁶ it has been shown that gastroscopy is of assistance not only in the diagnosis of carcinoma, but also in helping to determine the location and extent of the tumor, and in differentiating benign and malignant lesions. In the following case of advanced carcinoma the correct diagnosis was first made by gastroscopy.

CASE 6. W. A. (M. G. H. No. 84274) a 67-year-old man entered the hospital complaining of epigastric distress, anorexia and loss of weight of 4 months' duration. Physical examination showed a fatty epigastric mass 4 cm. in diameter with a ventral hernia.

X-ray examination on October 26, 1937 showed a normal esophagus. There was slight hypertrophy of the pylorus muscle, with asymmetry of the immediate prepyloric area. There was slight thickening of the rugae in this area. The whole process was probably due to localized gastritis. The pylorus opened readily. The cap was not deformed. The duodenum was not remarkable. There was marked tenderness above the antrum immediately above the palpable hernia. The examiner suggested checking the antrum 4 weeks after operation for repair of the hernia which was done on October 29.

On January 23, 1938 the patient was readmitted because of abdominal pain of 3 weeks' duration and further weight loss. In spite of these symptoms, the clinical impression was gastric neurosis. X-ray examination was repeated on February 1. It was impossible to palpate the stomach owing to extreme tenderness at the site of the operation. The patient fainted and the examination was discontinued but it was possible to demonstrate an oval filling defect in the antrum about 2.5 cm. in diameter and an elongated pyloric valve.

It was planned to study this defect further when the patient could withstand the procedure. In the meantime, gastroscopy to decide between malignancy, polyps or acute gastritis and ulcer was done on February 5. Preliminary drainage yielded 45 cc. of cloudy, shredded brownish material, which contained no free hydrochloric acid. The pylorus was well seen and appeared normal. The muscle of the sphincter of the antrum appeared like an incomplete circle, with no ring of peristalsis on the aspect toward the greater curvature. Peristalsis was passing over the antrum entirely normally except that no wave seemed to form or carry through on that side. On the greater curvature on the posterior wall in the body of the stomach was a very nodular partly ulcerating and partly necrotic lesion probably 5 cm. in diameter having the appearance of carcinoma. There were marked hypertrophic changes throughout the mucosa. There was little doubt that the patient had carcinoma, probably extending to within 3 or 4 cm. of the cardia.

A third x-ray examination was done on February 7 and showed a lobulated tumor mass occupying the posterior wall of the body of the stomach, where it was seen by gastroscopy. The upper lobe of the mass lay at the level of the cardia, the lower border in the region of the angle of the stomach. Examination was again difficult, owing to extreme tenderness as well as to the large amount of fluid in the stomach. The defect disappeared completely as soon as a little more barium was given. It was not attempted to demonstrate the polypoid lesion previously described in the prepyloric region. The findings were those of a lobulated tumor mass on the posterior wall and a polypoid lesion in the

antrum There was no evidence of involvement of the esophagus

On February 15 a total gastrectomy was performed. Exploration revealed a carcinoma high on the fundus of the stomach, extending to within perhaps 2 cm. of the esophageal opening. In the prepyloric region about 1 cm. from

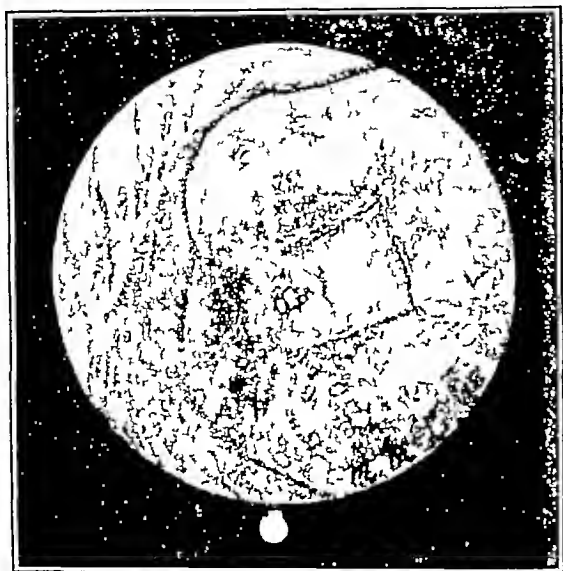

FIGURE 8 Case 6

Advanced carcinoma of the stomach, first demonstrated by gastroscopy and also accurately localized by gastroscopy

the valve was another carcinoma, about 1 cm. in diameter. The pathological report was adenocarcinoma. On February 28, the patient died of general peritonitis.

Gastroscopy here not only first showed the true nature of the disease, an advanced carcinoma (Fig 8), but also accurately demonstrated its proximity to the esophageal orifice. The clinical impression of gastric neurosis in this case emphasizes the danger of making such a diagnosis until all methods of examination at one's disposal have been employed.

CONCLUSIONS

Gastroscopy is a safe procedure, easily performed and well tolerated by most patients, and the information obtained from such an examination is of great value to the surgeon.

Since gastritis is the commonest disease of the stomach and massive hemorrhage may come from gastritis alone, all patients with unexplained gastrointestinal bleeding should have gastroscopic examination. The gastritis which frequently accompanies gastric or duodenal ulcer must be recognized and localized, particularly if surgery is under consideration. Since postoperative gastritis is a definite entity, satisfactorily studied only by gastroscopy and properly treated only after careful study, gastroscopic examination should always

precede surgery of the stomach following a previous operation.

In both gastric and duodenal ulcers the associated gastritis, which may seriously modify the medical or surgical management of the patient, is best studied by gastroscopy. Gastric ulcers not previously suspected have been demonstrated by gastroscopy. The gross appearance of the lesion, whether clean and sharply defined as in benign ulcer, or dirty and irregular as in malignant ulcer, and its response to treatment are points of very great importance that should be studied by gastroscopy.

Gastroscopy is of value in the diagnosis of carcinoma in determining its location and extent, and in differentiating benign and malignant lesions.

SURGERY OF THE STOMACH*

ARTHUR W ALLEN, M.D.†

BOSTON

LESIONS of the stomach requiring surgical intervention fall into two large classes. Those of a primarily benign nature include simple ulcer, gastrojejunal or anastomotic ulcer, gastrojejuno-colic fistula, polyposis, leiomyoma, gastritis and syphilis. The malignant disorders are carcinoma, sarcoma and lymphoma. It is sometimes impossible to be certain of the diagnosis by our present methods of study. The roentgenologist and gastroscopist, however, have narrowed this doubtful group materially during the last few years. At times the surgeon cannot be sure of the exact character of the tumor at the operating table without the aid of a pathologist. A frozen section, however, is not always feasible, since one hesitates to examine the main growth by biopsy. This makes it necessary to assume malignancy in any lesion under suspicion and to proceed with a wide resection.

*From the Surgical Department Massachusetts General Hospital Boston.
†Lecturer in surgery Harvard Medical School chief of the East Surgical Service, Massachusetts General Hospital.

PREOPERATIVE PREPARATION

Patients with surgical lesions of the stomach are likely to appear for treatment in a poor state of health, malnutrition, anemia and general debility are often present to an alarming degree. The very character of the ailment, whether it is due to a benign or a malignant condition, affects the most vital source of well being. Ingestion and assimilation of proper food elements are essential to normal physiology and biochemistry. Rarely does one find a patient with serious stomach disease who has been able to maintain an adequate diet up to the time of admission to the hospital. Thus it becomes necessary to evaluate carefully the nutritional state, the fluid balance and the blood chemical findings of these patients and to correct their deficiencies so far as possible before subjecting them to a surgical operation. In nearly every case a few days, and in some cases a few weeks, of preoperative preparation reduces the operative morbidity and mortality to a notable extent. Many skillfully executed surgical procedures have failed owing to the lack of reasonably normal resistance to infection or to pulmonary sequelae. The incidence of these complications can be materially lowered by restoration of a more normal chemical condition of the body, through the agencies of proper feeding, intravenous solutions and blood transfusions. If possible, one should not be content with combating anemia, fluid loss and protein deficiency by artificial methods alone. Laboratory findings may be within normal limits after these preparatory steps, and the patient may appear to be a good operative risk. The retarded and gradual postoperative feedings reduce this preoperative level so rapidly that failure may result in spite of heroic efforts. In certain cases, one may be justified in establishing a preliminary jejunostomy for feeding, or occasionally planning some other two-stage procedure. The first operation is directed only toward the relief of obstruction. The early administration of food and vitamins soon after operation makes a complementary jejunostomy for feeding of great value. The importance of establishing normal means of nutrition through the gastrointestinal tract cannot be overemphasized. Elements that protect against the trauma of surgery with its subsequent pulmonary and local infection are more adequately distributed to the body cells from this source than through the intravenous feedings available at present.

ANESTHESIA

A correct estimate of the anesthesia problem in gastric surgery is more important than it is

in many other fields. One needs relaxation to expose properly and correct adequately the situation at hand. The high incidence of pulmonary complications from procedures in this area is well known. Whether one chooses local, high spinal or a general inhalation anesthetic, one cannot eliminate entirely the effect of these upper abdominal surgical manipulations on the sympathetic nervous system and on the movements of the diaphragm. Splanchnic block, as advocated by Finsterer¹ and modified by Ogilvie² and others, certainly increases the ease of the operation and the comfort of the patient, and also seems to lower the incidence of postoperative pulmonary and abdominal complications. I use Ogilvie's splanchnic needle and instill 60 cc. of 1 per cent novocain and 0.25 per cent quinine urea solution into the retroperitoneal tissues above the pancreas, between the aorta and the vena cava. Rienhoff³ advocates the use of 100 cc. of 1-3000 Pontocaine solution for this purpose. Close attention to the details of local block of the abdominal wall and of the splanchnic area makes it possible in most cases to carry out a satisfactory gastrectomy without the addition of any inhalation anesthetic. Preliminary medication of $\frac{3}{4}$ gr of Pantopon one hour before operation is helpful. Neither more nor less of this drug, nor the use of other combinations apparently works so well. One needs a co-operative patient whose inhibitions have not been removed, and who is still sufficiently narcotized to bear comfortably a tedious ordeal. With the unco-operative or restless patient, nitrous oxide and oxygen may be added. An intratracheal nitrous oxide, oxygen and ether mixture in a closed machine gives ideal control, but it has not been established that this method has lowered the incidence of postoperative pulmonary complications. Statistics have been compiled to show that postoperative pneumonia was not reduced by local or spinal anesthesia on a mixed group of surgical patients.⁴ The fallacy of such data is obvious when one considers that local anesthesia was used mainly on the poor risk patients. The comparative freedom from postoperative complications in a small group of patients on whom local and splanchnic block anesthesia has been successfully carried out is striking. The technic is at first troublesome and tedious. Considerable practice is required to be reasonably certain of a smooth, painless procedure.

There certainly is less strain on the surgeon when anesthesia can be delegated to another. It is hoped that time will prove that spinal anesthesia with one of the longer acting drugs, such as Nupercaine or Pontocaine, will be as safe for the patient as is local and splanchnic block. So far, my experience

with spinal anesthesia for gastric surgery has been unsatisfactory, supplementary inhalation or Evipal anesthesia has been necessary in most cases. The deep narcosis produced by large doses of morphine and scopolamine, added to barbiturates preliminary to spinal anesthesia and used by some surgeons, seems rather hazardous. One wonders whether patients can tolerate so many drugs with sufficient regularity to warrant their use. Each surgeon must work out for himself the type of anesthesia that he can use with the greatest satisfaction. I certainly admit that there is a variety of choices. Since one third of the failures at the Massachusetts General Hospital have been due to pulmonary complications, it is necessary to attempt to meet this situation the best way one can. I believe that the anesthetic plays a greater role in postoperative pneumonia and pulmonary collapse than does any other single feature connected with the operation and convalescence. In districts where pulmonary complications are rare, the anesthesia problem does not seem to exist. There is also a marked variation in the experience of surgeons practicing in zones where pulmonary sequelae are common. This is better understood when one considers factors pertaining to the selection of patients for operation as well as the circumstances and surroundings in which one works.

BENIGN LESIONS

Ulcer is by far the commonest benign lesion of the stomach that requires surgical interference, although conservative treatment has effectively kept the majority of patients with this ailment in a reasonably good state of health. One must bear in mind that an ulcer may appear innocent by the various methods of study available and still be malignant. Such a patient must be kept under close supervision. Bed rest and a strict bland diet are essential for cure. X-ray examinations must be made as often as every three weeks until the ulcer is completely healed. Too often the clinician has been encouraged by the early loss of symptoms and an appearance by fluoroscopy that the ulcer is growing smaller. The patient under these circumstances may be discharged, to return in three months or later, at which time the lesion is found to be definitely malignant. Thus the opportunity for surgical cure may be lost. It has been shown that all those patients with cancer *in situ* have lived five or more years after surgical resection.¹⁰ One must be particularly suspicious of any ulceration, however small, in the immediate prepyloric region, since rarely does one find benign ulcer in this location. This is also true of ulcers of the fundus of the stomach. On the other hand, ulcerations of the lesser curvature are benign in

two thirds of the cases. This being the most frequent location for such a lesion, the impression is given that all ulcerative processes within the stomach may be considered benign until proved otherwise. The exact reverse of this attitude is the correct one to take, and no ulcer in such a situation should be lost sight of until the lesion has been proved benign.

In spite of the most careful conservative measures, some of these ulcers heal slowly or not at all, or have a distinct tendency to recur with little provocation. A certain number bleed profusely and suddenly as a large blood vessel becomes eroded. As in duodenal ulcer, these patients usually stop bleeding spontaneously on conservative measures if their blood vessels are young enough to allow the formation of a firm thrombosis. So rarely do patients under fifty years of age succumb to hemorrhage that one is always justified in treating this age group conservatively. In those in or beyond the fifth decade of life, one must be prepared to attack the source of the bleeding surgically. If one is going to rescue such an individual, one must make one's decision and proceed with surgery within forty-eight hours after the onset of bleeding. If one treats conservatively by bed rest and repeated transfusions until the patient has lost from his body cells those elements that can be replaced only by the absorption of food from the gastrointestinal tract, and then attempts to operate on him, the chance of success will be very poor. It is safe to say that such a patient with repeated bursts of bleeding, who has been kept alive for a week or more by transfusions, will have a better chance for recovery without surgical intervention. The operation may proceed well, and with plenty of blood transfusions the patient may appear to be in good condition afterward. His depleted state, however, makes the development of pulmonary complications and intra-abdominal infection most likely. If, on the other hand, a patient with acute massive hemorrhage who is otherwise in reasonably good health for his age is immediately hospitalized, the first step toward success has been achieved. By the blood count and hemoglobin determinations, the rate of the pulse and the height of the blood pressure, one can determine what to do next. The shock accompanying the first blood loss may pass quickly, and if the systolic blood pressure is above 70, blood transfusion should be withheld, since Nature is attempting to close the open vessel by clot formation and vessel constriction. Frequently an early transfusion, especially if given rapidly, will elevate the blood pressure and blow out the freshly formed thrombus. However, matched citrated blood must be prepared and kept in readiness in the refrigerator, and be used without delay if there

is evidence by collapse and lowered blood pressure that hemorrhage is continuing or that there has been a new burst of bleeding. If the patient does well and shows no further sign of active bleeding, within forty-eight hours, a conservative regimen may be continued. If, however, bleeding continues or recurs within this time limit, one may assume that one's older patient can be given a better chance for recovery by operation. In my own cases, I have found that one third of the patients beyond the age of fifty bleed to death from an ulcer that bleeds acutely and massively. If operation is undertaken in an orderly fashion on such patients within

upper posterior wall but has rarely become fixed to the pancreas, as it almost invariably does in the same type of ulcer in the duodenum. The eroded vessel is a branch of the left gastric artery. It is very difficult in the mobilized stomach to isolate and ligate these vessels above the lesser curvature when there is a penetrating ulcer. The safest procedure is to control the bleeding by tamponade while the duodenum and antrum are freed. An effective method of controlling the bleeding during the first part of the operation is that of having a second assistant keep firm pressure with his index finger on the ulcer through the anterior wall of

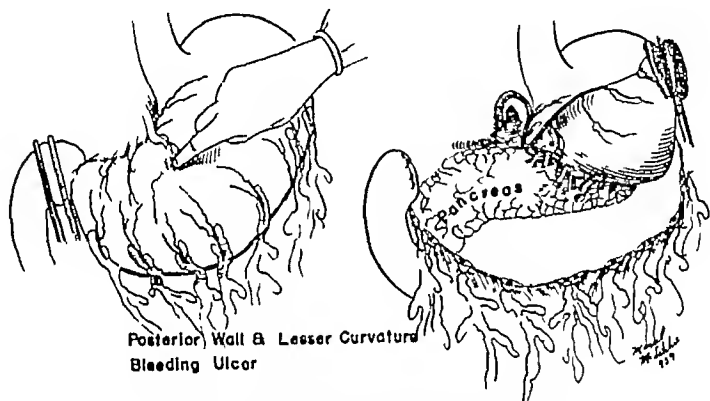

FIGURE 1 Method of Exposure of Left Gastric Vessels in Acute Massive Hemorrhage from Gastric Ulcer

Blood loss from the ulcer can be effectively controlled by an assistant while the stomach is being mobilized

forty-eight hours after the onset of hemorrhage the mortality is little if any higher than it is in gastric resection at a time of election.

The best method of attack on gastric ulcer with acute bleeding is a well planned subtotal gastrectomy. Gastrotomy and a direct attack on the bleeding point by cauterization or deep sutures will control the hemorrhage temporarily. Success of longer than temporary duration by this method can be attributed to Nature's own resources rather than to the operation. If one looks back on any successful outcome by such a maneuver, one will find that one has operated on a patient in the age group where spontaneous recovery could have been expected or on a patient with a small, shallow ulcer that has not eroded a large vessel or has been unusually fortunate. The reason for an indirect attack is sound when one takes into consideration the vessel involved. The ulcer is always on the lesser curvature, it may have extended to the

the stomach (Fig 1). After the distal end of the stomach and greater curvature have been freed and turned upward, it is a simple matter to locate and ligate the left gastric vessels. Transection of the stomach above the ulcer is then accomplished between clamps (Fig 2).

Continuity between the stomach and the intestine is best accomplished by gastrojejunostomy, since the resection should be high enough to include a large proportion of the acid-secreting cells in the fundus. The pylorus should also be removed in order to eliminate the cells of acid excitation. To perform a resection for ulcer, conservative enough to allow the Billroth I gastroduodenostomy, is to take unnecessary risks toward the development of future ulcerations. I prefer a short-loop posterior Polya type of anastomosis, which has given such uniform success that it seems to constitute a satisfactory method. In secondary ulcerations where the primary operation had been

made through the mesentery of the colon, I prefer to accept the disadvantages of a long-loop anterior anastomosis, rather than to subject the new suture line to the scar formation that would be produced by the ragged and traumatized opening in the mesentery. The convalescence at the start may be satisfactory, and it is easier to locate in case of the need of further intervention, but these patients in my experience are prone to have a sensation of heaviness and discomfort, with a tendency to regurgitate duodenal contents until they learn the secret of diet, posture and gravity. One could eliminate many of these early objections by doing an enteroenterostomy between the proximal and

FIGURE 2 Specimen of Stomach Successfully Removed for Acute Bleeding Ulcer of the Lesser Curvature

The open eroded vessel can be seen near the left margin of the ulcer crater

distal loops of the jejunum, and when this type of anastomosis is necessary in patients with cancer of the stomach, I invariably add this maneuver. In the patient with ulcer, however, enteroenterostomy should never be used, since it has been demonstrated by animal experiments and clinical experience that this is an ideal situation for the formation of anastomotic ulcer. In gastrectomy for all stomach lesions except those near the pylorus one will find the procedure simplified if the duodenum is freed and transected as the first step in the resection. The added exposure and control of the gastric segment make logical this reverse process to resection for duodenal and pyloric lesions.

Conservative operations for gastric ulcerations have been advocated. These include pyloroplasty with excision of a low anterior wall ulcer, pylorotomy or partial gastrectomy that includes only the ulcer area, V-shaped excision with gastroenterostomy, gastrotomy with cauterization and suture of the ulcer with gastroenterostomy, sleeve resection for ulcers of the pars media, and, in the earlier days, simple gastrojejunostomy or gastroduodenostomy. All these measures have produced successful results in the past. Most surgeons now believe that ulcers which will respond to such methods of treatment are also likely to do well on a conservative medical regimen. Also, one is not sufficiently satisfied concerning the question of malignancy until the pathologist has made sections from all parts of the lesion. One is often surprised to find that one's wide resection for a supposedly benign ulcer has been a happy choice since cancer cells are reported to be present.

In stomal ulcers, I believe that subtotal gastrectomy is the operation of choice. By this is meant a resection of two thirds to three fourths of the stomach. Often it is necessary to resect a segment of jejunum about the old anastomosis. This may be tedious, and the anastomosis between the divided ends should be the next step in the procedure. If the patient is bearing the operation well, one may proceed with the thenceforth simple gastrectomy. If the patient is a poor risk or is not standing the operation well, it is best to resect the old stoma in the wall of the stomach and leave the gastrectomy to a later date. One must be on guard lest the patient had his pylorus transected and sutured at the time of his gastrojejunostomy, since there was at one time a marked preference for this procedure of von Eiselsberg.⁶

In gastrojejunocolic fistula, one meets a situation demanding a great deal of care and thought. These patients are usually in a poor state of nutrition. Often a prolonged period of rest and diet will get them into a suitable state for surgery. A preliminary jejunostomy for feeding solves the problem adequately and should be used more often. Pfeiffer⁷ conceived the idea that the malnutrition was due to the emptying of colonic contents into the stomach rather than to the loss of food directly into the colon. Therefore he performed a right colostomy on 3 such patients, and found that they all gained weight and became good operative risks in a few months. He was also agreeably surprised to find at the second operation that the inflammatory reaction about the stoma had apparently been greatly reduced. Lahey⁸ has accomplished the same purpose by a preliminary ileosigmoidostomy. I⁹ have advocated an aseptic resection of the fistula and in 7 consecutive cases have lost only 1 patient, and

that from pneumonia. Doubtless a preliminary operation of diverting the fecal stream will make the resection of the stoma safer, and with the lack of contamination one might proceed with subtotal gastrectomy at the same time. If the fistula alone is resected and normal continuity is restored,

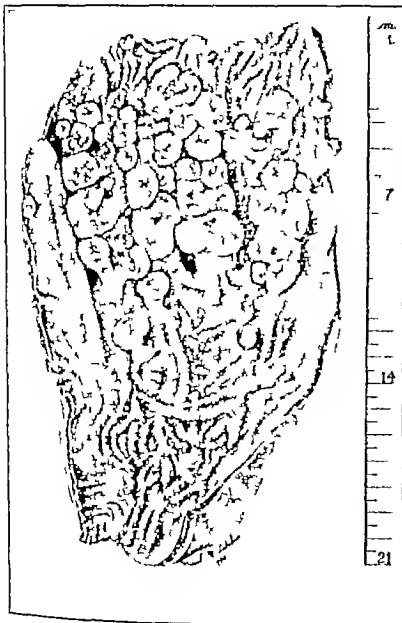

FIGURE 3. Multiple Benign Polyps of the Stomach Requiring Subtotal Gastrectomy

An additional polyp was removed with the cautery from the remaining proximal stomach segment prior to restoration of continuity

the patient will almost invariably reactivate his original duodenal ulcer. Thus, whatever procedures are carried out, the final one should include an elimination of that part of the stomach from the junction of the proximal and middle thirds, to and including the first portion of the duodenum. I am coming to believe that, if one is tempted to utilize the Finsterer¹⁰ resection for exclusion operation for duodenal ulcer, Bancroft's¹¹ modification of removing the mucosa of the remaining distal segment of stomach should be included. The activating cells in the antrum are likely to overstimulate the remaining acid cells in the proximal third of the stomach, with resulting recurrence of ulcer at or above the anastomosis.

Polyps of the stomach, like those elsewhere in

the gastrointestinal tract, are prone to become malignant. Benedict and Allen¹² found that 41 per cent of the gastric polyps at the Massachusetts General Hospital had degenerated into cancer. It is therefore rational to subject a patient with gastric polyps to surgery. Usually these lesions are multiple, and when such is the case one should resect the portion of the stomach involved. This may mean the distal third or distal half only, but occasionally the procedure necessitates a very radical subtotal resection (Fig. 3). If the polyps are single they may have a long stalk, and the tumor may be located where it can occlude the pylorus intermittently. In cases where there is a single pedunculated polyp or a few such lesions not far apart, one may eliminate them by opening the anterior stomach wall and attacking the tumors separately. It is always wise to clamp the base of the stalk well

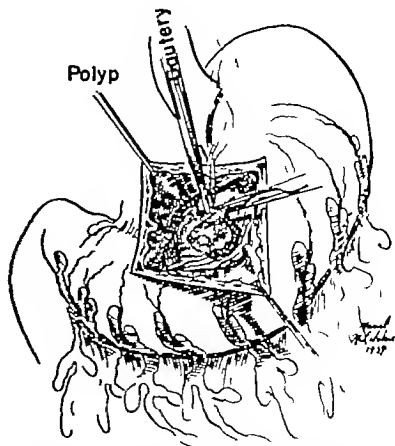

FIGURE 4. Single Polyp of the Stomach Removed with Actual Cautery Through a Gastrostomy Opening

into normal mucosa and to remove the lesion with the actual cautery (Fig. 4). If such a polyp is cancerous it is apt to be of a low grade of malignancy, and although the cancer cells rarely extend into the base of a pedunculated polyp, excision with the cautery gives added assurance that no malignant cells have been left behind.

Leiomyoma of the stomach gives the roentgenologist a characteristic picture. The rounded, mound like smooth tumor with a central depression makes the diagnosis unmistakable. Most of these patients seek advice on account of profuse bleeding. They are usually referred with the diagnosis of ulcer or cancer. They have rarely had gastric dis

tress from food, emotion or fatigue. The hemorrhage is prone to be sudden and profuse, owing to an erosion of the central part of the tumor into a nearby blood vessel. Fatal bleeding occurred in 1 out of every 4 of such cases admitted to the Massachusetts General Hospital in the ten-year period, 1923-1932. In 1 of these patients the lesion, which was located in the pars media, was eliminated by a sleeve resection (Fig 5). In 2 others it was pos-

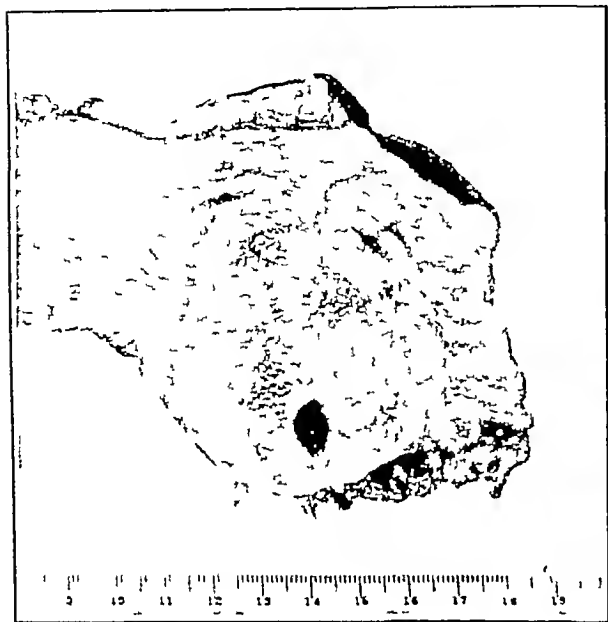

FIGURE 5 Typical Leiomyoma of the Stomach

Note the mound like appearance with the broad base. The dark spot in the center represents a crater which led to an exposed vessel from which profuse hemorrhage had taken place.

sible to remove the tumor with the actual cautery through a gastrotomy, these lesions were high and near the cardia, and were fortunately smaller than the others in the group. In all the other cases that were operated on, it was necessary to resect a segment of the stomach in order to obtain a satisfactory margin of normal tissue. These tumors are usually benign, and complete local excision results in cure.

Gastritis of the hypertrophic type is appearing in the records of the Massachusetts General Hospital much more frequently than it was a few years ago. This has been brought about by better x-ray methods and by the use of the gastroscope. Benedict¹³ has shown that the diagnosis can be made by gastroscopy in cases where the roentgenologist is in doubt. I am sure that many of the distressing symptoms associated with ulcer are due to the accompanying gastritis. There are, however, many patients who have no demonstrable ulceration but have a marked hypertrophic gastritis. One of the

chief sources of difficulty in such a case is repeated profuse bleeding, while other patients bleed more or less gradually and over long periods of time. By far the majority of such cases respond well to a conservative regimen. This includes not only proper dietary measures but rest, freedom from worry and abstinence from alcohol and tobacco. Also, the water-soluble vitamins may play a role in recovery. The marked hemorrhagic tendencies which these patients have make me think that they should all have the blood-prothrombin level determined, and that, if it is found to be low, vitamin K should be given a trial. In patients who have periods of bleeding from gastritis, due to faulty mechanics of previous surgery, radical operation offers the most practical means of restoring them to health (Fig 6). It is my belief that one rarely meets a situation where gastritis alone warrants surgical intervention. If such a patient is invalided and needs to earn a livelihood, and

FIGURE 6 Subtotal Gastrectomy for Repeated Episodes of Bleeding from Gastritis

Pylorectomy, with a Billroth II operation, had been done ten years previously.

cannot for mental, social or economic reasons maintain comfort, he should be given the benefit of a subtotal gastrectomy. The relief obtained in patients who have this operation for a small ulcer associated with extensive gastritis makes me think that the operation is occasionally justified for gastritis alone.

Syphilis of the stomach may be intractable to medical treatment. Also, it is not always possible to be certain that the lesion is not cancer. Therefore, occasionally the surgeon is consulted in such cases. Usually one operates under the impression that the lesion is malignant, and finds the true diagnosis only with the aid of the pathologist. If the lesion persists in spite of adequate antisyphilitic treatment, the clinician begins to

suspect that cancer is the cause. If one could be sure that one were dealing with a gumma and thought that resection was the best method of making the patient comfortable, a less radical operation would be done. In the doubtful cases, however, one proceeds with a radical excision, including the involved lymph nodes. A positive Wassermann or Hinton test does not exclude a diagnosis of cancer of the stomach.

MALIGNANT LESIONS

The statistics of the United States Public Health Service¹⁴ for 1936 report 27,241 deaths from cancer of the stomach in the United States. This represented approximately 19 per cent of all the deaths from cancer reported. In all likelihood these figures do not give an exact picture of the situation, since doubtless many deaths from cancer of the stomach are attributed to other causes. They are of importance, however, from a comparative viewpoint, and show that more people die of cancer of the stomach in the United States than from any other form of malignant disease. Livingston and Pack¹⁵ have recently published a most interesting monograph with much valuable data on cancer of the stomach.

According to Parsons and Welch,¹⁶ during the years 1927 to 1936, 691 patients with cancer of the stomach were admitted to the Massachusetts General Hospital, of these, only 441 were offered and accepted surgical treatment. In the remaining number the disease was found to be so far advanced that nothing could be done for them. In addition to physical findings of distant nodes, usually demonstrated by rectal or pelvic examination, one now has the aid of peritoneoscopy in determining the inoperability of intra-abdominal lesions. Since there is a high mortality from exploratory laparotomy in far advanced cases of cancer of the stomach, one welcomes this simple and effective means of eliminating unnecessary operations. Benedict¹⁷ has been able to determine the operability in approximately 90 per cent of the doubtful cases subjected to peritoneoscopy. It is easy to ascertain the presence of peritoneal implants and liver metastases by direct vision, but impossible to be sure always of pancreatic involvement and fixation.

Of the 441 patients subjected to operation in this group, 171 were considered resectable, and 75 per cent of these failed to leave the hospital alive. 143 were simply explored, and 15 per cent of these died, 127 were given the benefit of a palliative operation, with a mortality of 25 per cent. In the resected cases, 21 per cent of the patients were alive at the end of five years. Ex-

cluding the postoperative deaths, there were 32 per cent of five year cures. In the five year survivals, it is interesting to note that the earlier the lesion the higher the chance of cure, but those patients with symptoms of six months or less were found in a much less favorable condition than were those with symptoms for a year or more. All the patients with carcinoma *in situ* and 62 per cent of those whose nodes were not involved lived for five years or more. Only 16 per cent of those with nodal involvement and 8 per cent of those with fixation of the tumor to other structures lived for five years or more.

Parsons¹⁸ reported on the cases of carcinoma of the stomach entering the Massachusetts General Hospital from 1922 to 1926. In comparing his figures with the more recent ones, we find that there has been an increase of resectability from 27 to 37 per cent, and that the operative mortality has been reduced from 38 to 25 per cent. Although this means a greater number of such patients alive at the end of a five year period, the actual percentage of cures by operation was unchanged. In other words, the better diagnostic and educational methods accounting for a greater number of early cases have been offset by the increasing tendency on the part of the surgeon to attempt extirpation of the advanced lesion.

Surgery is the only form of treatment that has so far been found effective against this disease. Therefore one must bear in mind the possibility of this common ailment, and make diagnoses early enough to increase the number of cures. Ulcerative lesions of the stomach must be most carefully studied and closely followed. If the tendency to advise surgery in a doubtful benign ulcer should become more prevalent, it would in my opinion result in a greater number of lives spared from malignant disease of the stomach. Authorities vary in their opinion concerning the development of cancer in a benign ulcer. It must occur in a certain number of cases, and the percentage is probably greater than the operative mortality of partial gastrectomy for an early lesion.

Resection for cancer should be undertaken with every safeguard for the patient, and should be planned in such a manner that not only the primary lesion but also the nodal areas are included. I have adopted the method of freeing the great omentum from the transverse colon and thus removing lymph nodes that were heretofore left behind. In most cases this actually simplifies the procedure since one can control the blood supply of the whole greater curvature by two principal ligatures on the gastropiploic vessels. After the omentum is freed the duodenum is transected and

the left gastric vessels can then be ligated near their source, thus removing the nodes of this entire area. The stomach should be sectioned between clamps well above the involved area. If clamps are not used, there is an unnecessary amount of soiling from the infected contents of the stomach. Unlike ulcer cases, these cases with malignant disease of the stomach show little or no hydrochloric acid, and therefore virulent microorganisms are usually present. One may try to sterilize such a stomach before operation by washings with dilute hydrochloric acid or by the administration of sulfanilamide. It has been my experience, however, that there is little evidence to support the efficacy of such procedures. The anastomosis of the remaining segment of stomach should be made to the jejunum, since rarely will an adequate resection leave a suitable amount for anastomosis to the duodenum. The posterior Polya short-loop anastomosis is advised if there are no technical reasons against it in any specific case. If there remains a short high segment of stomach and there has been some trauma to the transverse mesocolon during the dissection, it is then better to do a long-loop anticolic anastomosis. Only in the cancer cases can enteroenterostomy between the long proximal and distal limbs of the jejunum be advised. This procedure makes the convalescence easier and eliminates the discomfort of a full duodenum after eating, as well as the disagreeable regurgitation of bile on lying down that many of these patients have. A jejunostomy for feeding is well worth while in these depleted patients. Through this one can administer fluid, food and vitamins within forty-eight hours after the operation. Syphonage from the stomach, if there is any amount over a period of days, can be added to the feedings. The patient can thus be kept nourished until he is able to take an adequate diet by mouth (Fig 7). The Levine tube is left within the remaining segment of stomach until all physiologic ileus has passed, and until one is sure that secretions and food are passing down through the intestinal tract. This may be a matter of several days, usually however, the tube can be removed within three or four days.

Occasionally one finds it necessary to include a segment of the transverse colon in the resection, owing to involvement by direct extension or to interference with its blood supply. In such cases I have usually proceeded with a primary aseptic end-to-end anastomosis of the viable bowel ends, adding a complementary cecostomy. Although many patients withstand this procedure well, it is my belief that there would be less risk by not prolonging the operation to this extent. One might be content simply to bring the bowel ends out through the abdominal wall with the clamps still

in place. It would usually be possible to free the flexures of the colon and suture the two limbs together, leaving a segment at each end, to be separated slightly by abdominal wall sutured between them. This would allow the crushing of the spur within the peritoneal cavity at a later date, as ad-

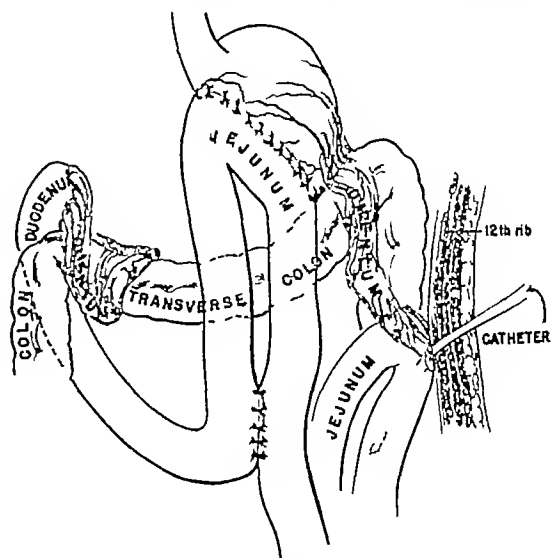

FIGURE 7 Radical Subtotal Gastrectomy for Cancer

The omentum has been removed. The remaining segment of the stomach is too small and too high for satisfactory anastomosis through the mesocolon. The two limbs of the long loop anticolic anastomosis are joined by an enteroenterostomy. Complementary jejunostomy for early feeding is an added safeguard.

vocated by Devine¹⁹ in his defunctioning colostomy.

One may find the tumor fixed to the pancreas. I have frequently removed such attachments with the cautery without mishap. However, attempts in 3 successive cases to extirpate a large segment of the body of the pancreas with the entire stomach have failed—in 2 cases owing to subsequent pancreatitis and in 1 to pneumonia. A proper system of drainage of the pancreas in such a case might result successfully.

Surgeons at the Massachusetts General Hospital have now extirpated the entire stomach in 39 cases. All these operations were for cancer, except in 2 cases, in one of which it was for lymphoma and in the other for a large benign ulcer which was thought to be malignant. The operative mortality has remained at about 50 per cent. One patient lived four years and eight months after operation, and was well and able to work at his regular occupation for most of this time. Respite of varying intervals rewarded the others, and all were spared the very disagreeable slow starvation with persistent nausea that awaits the inoperable patient. The technic of the procedure has been previously described.²⁰ It has been changed very little, other than to include the whole omentum in the resec-

non. The added support of the jejunal loop gained by suturing it to the diaphragm about the end-to-side esophagojejunal anastomosis has been most satisfactory. Suction, maintained from above through a Levine tube lying at the open end of the esophagus, has reduced the incidence of infection. A large enteroenterostomy between the two limbs of the jejunal loop has increased the comfort and safety of the operation, allowing this loop to function more or less like a new stomach. A jejunojejunostomy for feeding has made it possible to sustain these patients satisfactorily until an adequate diet can be taken by mouth. The smoothness of convalescence in most of these cases is remarkable.

Palliative operations for carcinoma of the stomach are disappointing. In fact, a palliative gastroenterostomy adds little if anything to the patient's comfort, because it does not relieve the persistent nausea or distaste for food and rarely prolongs life to any extent. The best palliative procedure is the exclusion operation of Devine²¹ (Fig. 8). This is possible in certain growths involving the lower half of the stomach but so fixed to the liver and pancreas as to make resection impossible. If one can transect the stomach through healthy tissue above the growth, turn in the distal segment and anastomose the normal proximal portion to the jejunum, the patient will get relief of his symptoms. He will often gain weight and obtain a respite of several months. Palliative jejunostomy for feeding is hardly justifiable, in that the symptoms produced by the lesion in the stomach persist, and rarely can a patient be improved in strength and happiness by such a procedure.

Lymphoma, sarcoma and leiomyosarcoma of the stomach should be treated by resection when feasible, since these tumors are often slow growing and long periods of health and comfort may be obtained. In cases of lymphoma, postoperative x-ray therapy is indicated, some of these patients have been kept working at their regular occupations for several years by this combined attack. A second resection of the recurrence is not rewarded by the same respite as that gained by the first procedure, as apparently the host's natural resistance against the disease finally breaks down. Radiation has apparently less effect in the later recurrences, after repeated attempts at retardation have been made by this method of treatment.

SUMMARY AND CONCLUSIONS

Ulcerative lesions of the stomach should be looked on as malignant until proved benign. This means careful treatment, often repeated roentgenograms and very close observation until the lesion is healed.

Polyps of the stomach must be considered as pre-cancerous lesions and extirpated.

Leiomyomas should be resected with a wide margin as soon as the diagnosis is established. Massive hemorrhage is apt to be the first symptom.

FIGURE 8. Transsection for Exclusion of Lesion Too Invasive for Resection.

This is also a good method of dividing the operation into two stages in a poor risk patient.

unless the lesion encroaches on the cardia or the pylorus.

Hypertrophic gastritis rarely causes sufficient disability to warrant surgical intervention.

Carcinoma of the stomach is a commoner cause of death than any other form of cancer in this country. Surgery is the only means of cure at this time. Early diagnosis should be the ambition of every clinician. The earlier the lesion, the lower the operative mortality and the greater the chance of cure.

SURGERY OF THE DUODENUM*

FRANK H LAHEY, M.D.†

BOSTON

IN DISCUSSING surgery of the duodenum the subject of cancer does not have to be considered as it does in other portions of the intestinal tract, since the incidence of carcinoma of the duodenum is reported as 1 in 31,000 autopsies from the General Hospital in Vienna. The essential subject, I think, for me to discuss is that of duodenal ulcer because it represents the commonest, the most distressing and the most serious duodenal lesion.

Since one must draw deductions largely from his own personal experiences, it is of importance to present figures representing our experience at the Lahey Clinic with this lesion. The clinic has now managed, in bed in hospitals, 3670 patients with duodenal ulcers. It is important in discussing surgery of the duodenum to state that of this number only 8.2 per cent were submitted to operation. These figures are interesting in that they indicate a change from our former attitude regarding the incidence of surgery in duodenal ulcer.

From the Department of Surgery, Lahey Clinic, Boston.

†Surgeon in chief, New England Deaconess and New England Baptist hospitals, director, Lahey Clinic, Boston.

Although we have operated on only 8.2 per cent of the patients with duodenal ulcers, this does not by any means indicate that all the others are entirely well. It does mean, however, that they are so well that there is no urgent demand for operation. They are not suffering from recurrent hemorrhage, the ulcer has not perforated, they are not suffering from pyloric obstruction. Neither are they bothered by symptoms sufficient to interfere with their daily enjoyment of life. The patients who had incapacitating symptoms constitute the 8.2 per cent who were operated on.

Our change in attitude within the last few years regarding the type of operation is also of interest. Previous to 1930 we did three resections to every seven conservative operations in all types of ulcer, gastric and duodenal. Today in duodenal ulcers alone we do seven resections in contradistinction to every three conservative operations. It can be seen that in the last ten years the figures as to conservative and radical operation have been completely reversed.

We do not disagree with the statement already made at this meeting. We believe that when men have had enough experience with this lesion, or for that matter with almost any other, there may be minor differences of opinion regarding the management of lesions, but not major differences about their general management. Therefore, I agree with practically everything that Dr Jones has said.

I know of nothing which has been of greater value to us in the care of patients with peptic ulcer than medical opinions concerning preoperative preparation and the separation of cases into those desirable for surgery and those not requiring surgery, through a trial of medical management and not through primary surgical selection.

I agree with Dr Jones that gastroenterostomy is not a desirable operation. I have repeatedly written and firmly believe that this is not an operation that should be applied routinely to patients with duodenal ulcer. On the other hand, I also agree with him that if the patient is a bad risk it is better to have him alive with a gastroenterostomy, even if the incidence of a subsequent gastrojejunal ulcer is, as we believe it to be, 16 per cent, than to submit him to a more ideal operative procedure that has a hazard, in cases not acceptable for partial gastrectomy, which is altogether too great to be reasonably accepted.

For that reason I feel strongly that the selection of the type of operation for duodenal ulcer must always be made not in the terms advocated by so many European surgeons, namely 100 per cent gastrectomies, but in terms of how well the individual

will stand the operative procedure. That can often be settled with finality only when the abdomen has been opened, when the lesion has been visualized and when all the risks involved have been evaluated. For that reason my attitude toward the operative treatment of duodenal ulcer has always been, not that subtotal gastrectomy should be performed in every case, but that it should be employed when it can be done with a reasonable risk. When this risk seems too high, some of the more conservative, even if less satisfactory, operative procedures should be employed.

As a result of our not inconsiderable experience with subtotal gastrectomy for peptic ulcer—296 operated cases,—we have arrived at quite definite convictions regarding the operative procedure. When we do a subtotal gastrectomy it is not a conservative operation, as will be seen in the illustration (Fig. 1). It includes the removal of three

fourths to four fifths of the stomach. That can often be settled with finality only when the abdomen has been opened, when the lesion has been visualized and when all the risks involved have been evaluated. For that reason my attitude toward the operative treatment of duodenal ulcer has always been, not that subtotal gastrectomy should be performed in every case, but that it should be employed when it can be done with a reasonable risk. When this risk seems too high, some of the more conservative, even if less satisfactory, operative procedures should be employed.

I have noticed in the literature and have recently heard a paper advocating limited pylorotomy for ulcer, this does not seem to me a sound procedure. I think that the accumulated evidence today indicates that, if subtotal gastrectomy is done for ulcer it should be radical. It has been the experience of nearly everyone who has undertaken this operation that with a limited experience, there was a tendency to do conservative resection, and that the end results in these cases were not so satisfactory as those in cases in which radical and high partial gastrectomy was done.

I should like to make one or two points regarding the general management of duodenal ulcer.

The first has to do with obstruction. We have, I am sure, made more mistakes, caused more unnecessary delay and incurred more expense for patients in the matter of obstruction than in almost any other complication occurring in patients with duodenal ulcer. These patients can be put to bed, and under ideal conditions of rest and neutralization an obstructed pylorus can be so relaxed that food will pass through quite satisfactorily. When, however, they go back to work and are under stress and strain, and with the dietary conditions under which they must live, many of them still have recurrence of pyloric obstruction. Because of the fact that we have been able to make the pylorus drain satisfactorily under these ideal conditions, we have in the past, I am sure, occasionally unduly delayed an operative procedure which was probably necessary.

Because of the above situation we have had to set up a definite plan, endeavoring thus to avoid unnecessary expense and delay. Patients who have had obstruction twice and been relieved under rest and neutralization, should obstruction occur a third time under any condition become candidates for surgery. Thus, we believe, is a fair and reasonably conservative approach to the problem of obstruction, and one that tends to prevent unnecessary delay in its surgical management.

The next question is that of perforation of a duodenal ulcer. One hears at times considerable discussion about technical measures for the management of the ulcer itself at the time of perforation. We feel very strongly that our obligation to a patient at a time when the ulcer perforates is to get him through alive. We do not recognize any obligation at this time to undertake procedures such as subtotal gastrectomy directed toward the removal of the ulcer and permanent cure of the

FIGURE 1 Postoperative X-ray Film

This shows the small amount of stomach left after subtotal gastrectomy for ulcer. Note the satisfactory drainage with Hofmeister anastomosis also the complete absence of enteroenterostomy and that the contents of the proximal loop of the jejunum empty into the stomach for neutralization.

fourths to four fifths of the stomach. When we perform subtotal gastrectomy for ulcer we do it for two reasons: to get rid of a large proportion of the acid-secreting glands, and to put back into the stomach by means of the anastomosed jejunum the alkaline jejunal contents. Both these factors are calculated to lower gastric acidity. As we have viewed our cases in terms of good results, we have

condition. From our experience with these cases, we believe that there are sound reasons for this. Not all patients with perforated duodenal ulcers can be operated on early enough so that the hazard to life itself from merely closing the ulcer is not considerable. We are fully convinced that one cannot add the risk of subtotal gastrectomy in the presence of a perforated ulcer without materially increasing the mortality rate. In addition to that, many patients with perforated duodenal ulcers have never had a really adequate trial of medical management before the perforation occurred. Under these conditions one would subject a patient to a major surgical procedure without being certain that the ulcer could not have been managed medically after the perforation had been closed. We are very sure that our first obligation is to save the patient's life by simple closure of the ulcer, unless this produces obstruction. Our next obligation is to determine by an adequate trial of medical management, after the patient has recovered from the perforation, whether the ulcer can be healed without operation. Then, should medical management fail, radical operation in the form of subtotal gastrectomy should be carried out, if the patient's general condition and the location of the ulcer permit.

The points regarding hemorrhage have been well brought out in this discussion. Most hemorrhages occur in duodenal ulcers because most ulcers are duodenal. We have had 9 cases of duodenal ulcer to 1 of gastric ulcer. It is, therefore, largely in this field that the problem of hemorrhage will be met.

As to bleeding from a duodenal ulcer, there are two outstanding points. One is that if operation for hemorrhage is to be undertaken the decision must be made within the first forty-eight hours. The other is, of course, as has been so well demonstrated everywhere, that hemorrhage in patients over fifty years of age is more serious than that in younger patients.

As regards the first position, it has been shown by Finsterer, Taylor and others, that if operation is performed on patients who are having massive recurring hemorrhages from a duodenal ulcer after forty-eight hours, the mortality will be almost prohibitive. When patients have bled recurrently over a period of two days, even though they are repeatedly given transfusions, they are in no condition to withstand major surgical procedures, as a matter of fact, they are usually operated on at this time as a last resort when they are in extremis.

What one should do, therefore, is to make up one's mind within forty-eight hours whether or not a given case is the occasional type of recurrent massive hemorrhage in which it is justifiable to

make an attempt at surgical control. I know of no place in surgery where greater judgment is necessary. This situation has the undesirable aspect of leaving the surgeon with a wish that he had not operated should a fatality occur, and a wish that he had operated should a fatality follow nonsurgical intervention. The outstanding established feature of this situation is, however, that the decision should be made within forty-eight hours.

When Dr. Jones mentioned the fact that this was a technically difficult operation, he brought up a very important point, and one which is extremely difficult to discuss, particularly for anyone in my position. Nevertheless, for the sake of honesty and frankness this needs to be done. I know of no operative procedure that I have undertaken that has been harder to standardize, and in which it has been more difficult to lower the mortality—1 death has occurred in our last 88 consecutive subtotal gastrectomies. There are so many surgeons today who are able to do subtotal gastrectomy for ulcer with a reasonable mortality that I am sure that if I stress the fact that to obtain low mortality rates with this procedure requires a large operative experience with this lesion, I shall not be thought unjustly critical.

It is not the mere sewing that governs the mortality in this operative procedure. It is the management of the ulcer itself, the detachment of the posterior wall ulcer from the head of the pancreas, the decision as to whether or not the ulcer is located so close to the entrance of the common bile duct into the duodenum that it cannot be successfully removed. It is the ability to do sufficiently high resections of the stomach without permitting spilling and soiling from gastric contents. It is the technical management of oozing and bleeding in the head of the pancreas, and particularly the successful management of anesthesia. There are a great number of factors that bring about the mortality in subtotal gastrectomy. It is in my opinion an operation in which experience pays higher dividends than is true of almost any other operation with which I have dealt.

I have listened with interest and well-deserved respect to Dr. Allen's discussion of local anesthesia, and I am sure, basing my opinion on a considerable experience with it, that it is not the best anesthesia for subtotal gastrectomy. I have arrived at this conclusion only after having done a considerable number of subtotal and total gastrectomies with local anesthesia, field block and splanchnic block. There is no doubt in my mind that this type of anesthesia is far superior to any obtained with the general anesthetics, such as ether, intra-tracheal ethylene and intratracheal cyclopropane. In our experience with 415 subtotal and total gas

trecomies for ulcer and cancer we have employed all types of anesthesia,—ether anesthesia, regional and field block anesthesia, with the later addition of splanchnic block, the further addition of intratracheal cyclopropane and ethylene, together with regional anesthesia and splanchnic block. We have for the last four years performed all total and subtotal gastrectomies under 1 1500 Nupercain spinal anesthesia. This type of spinal anesthesia, which was so hazardous when given using a concentrated Nupercain solution, is now, with dilutions of 1 1500, very safe in the hands of those who are skilled and experienced in its administration and is the type of anesthesia now routinely employed in all our total and subtotal gastrectomies.

The proper dose of Nupercain solution is determined from the height and sex of the patient. For operations in the upper part of the abdomen the dosage is as follows: 16 cc. for a five-foot woman and 17 cc. for a five-foot man, for every three inches over five feet, 1 cc. is added, 20 cc. is the maximal dose. For anesthesia in the lower part of the abdomen, divide 100 by the number of the uppermost thoracic nerve segment which is to be anesthetized. The result is the quantity, in cubic centimeters, of Nupercain solution to be used.

Nupercain anesthesia, with 1 1500 dilution, will ensure complete relaxation for two to three hours, and even at times for three and a half. It will produce a slight drop in blood pressure than will Pontocaine or novocain. In our hands it has played a very important part in lowering the mortality and morbidity in these cases, owing to the prolonged relaxation that it produces. I believe that anyone who will try this type of spinal anesthesia, provided it be given by someone expert in its use, will find that it makes possible such relaxation that these difficult technical procedures can be accomplished with greater ease, and thus with fewer postoperative complications and with a lower mortality rate, than with any other type of anesthesia. When one adds to it, as we so frequently do, in travenous Evipal or Pentothal, it becomes from the patient's point of view, almost ideal.

In Figures 2 and 3 is shown the so-called resection by exclusion, as advised by Finsterer. It is an operation that has definitely lowered the mortality rate of subtotal gastrectomy in some cases of very adherent and indurated duodenal ulcers of the posterior wall with which we have to deal. One of the difficulties in the management of an occasional patient with an eroding duodenal ulcer of the posterior wall is that the ulcer and the induration about it have so taken up the duodenal wall that the ulcer is very close to the ampulla of Vater. If it were removed, insufficient duodenal stump

would remain with which to accomplish safe inversion and safe suture of the duodenum. One of the postoperative complications that has resulted in

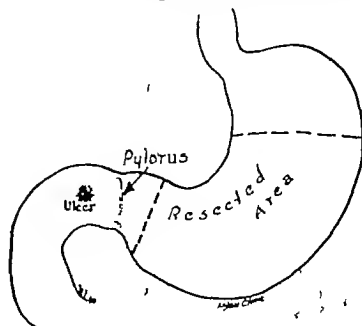

FIGURE 2. Resection by Exclusion (Finsterer)

The area between the dotted lines represents the portion of the stomach to be removed. The stomach is transected at the prepyloric line and turned so, the ulcer and pylorus remaining intact and unremoved.

fatalities in subtotal gastrectomy for duodenal ulcer has been duodenal fistula. This has not occurred in our hands since we have left the ulcer in situ in those cases in which removal of the ulcer and

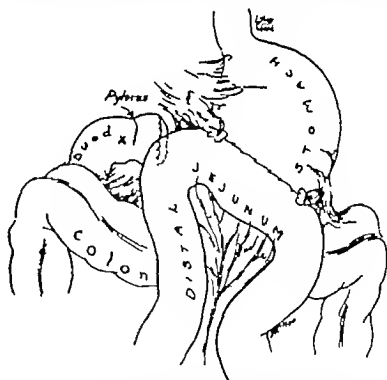

FIGURE 3. Resection by Exclusion (Finsterer)

Note the duodenal stump with ulcer unremoved and the stomach transected prepylorically and inverted. Also note the high subtotal gastrectomy with the remainder of the stomach and the high antecolic Hofmeister anastomosis.

duodenum would have left insufficient duodenum for safe closure. In those cases in which the duodenal ulcer could be removed we have always dissected enough of the duodenum from the pancreatic bed so that it could be safely inverted.

As shown in Figure 3, with resection by exclusion as advised by Finsterer, the stomach is cut

across just proximal to the pylorus and is inverted at this point. A subtotal gastrectomy is then done on the remaining portion of the stomach, accomplishing quite adequately the two desirable factors

FIGURE 4 *External Duodenal Diverticulum*

This is shown within the dotted area, and is safely resectable. Note that the neck of the diverticulum runs behind the duodenum.

in subtotal gastrectomy: removal of a large percentage of the acid-secreting glands and the introduction of alkaline jejunal contents into the stomach. In 21 cases in which this operative procedure has been done there has been one recurrent duodenal ulcer (relieved medically), and the end results have been quite as satisfactory as those in the cases in which the ulcer has been removed.

There will always be, as has been pointed out, some minor disagreement on the part of all surgeons as to the management of these operative procedures. One must, however, have very good reasons for rejecting methods which have already been established. We do not do the posterior anastomosis of the jejunum to the stump of the stomach, as described by Dr. Allen. For a number of years in our cases of subtotal gastrectomy antecolic anastomoses have been done. A long loop of the jejunum has been mobilized and anastomosed to the stomach anterior to the transverse colon. We do no enteroenterostomies between these two long antecolic loops of jejunum. We have given up posterior anastomoses for two reasons. We believe that obstruction takes place less frequently after operation when the loops are brought in front of the transverse colon than when they are passed behind the transverse colon, where there is more opportunity for them to be caught up in adhesions

and exudate and become obstructed. Second, if a gastrojejunal ulcer occurs in the gastric stump after subtotal gastrectomy,—and, no matter what any one says, it will occasionally occur,—reoperation is much easier to perform with the long antecolic jejunal loop than with the posterior anastomosis. In cases in which posterior anastomoses have been done, the inflammatory exudate about the recurrent ulcer is deep on the posterior wall of the abdomen at which point it is extremely difficult to deal with. With antecolic anastomoses, it will be just beneath the abdominal wall anterior to the colon and much easier to approach. We do not do lateral anastomoses between the two loops of jejunum because, if this is done, one essential

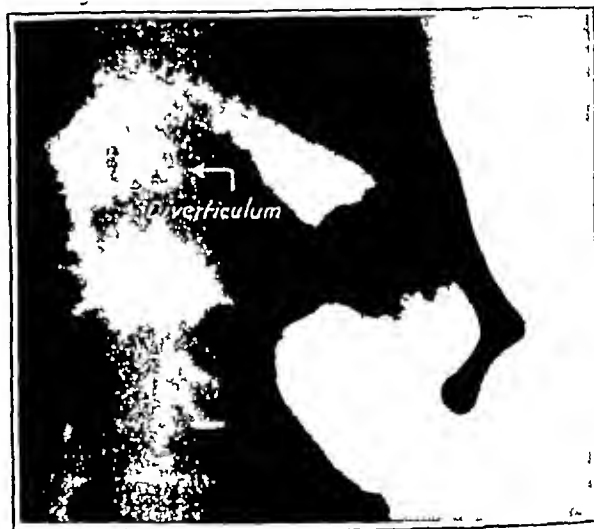

FIGURE 5 *Internal Duodenal Diverticulum*

This arises from behind the duodenum, enlarging inwardly into the head of the pancreas. These are most difficult and dangerous to remove.

principle in the treatment of peptic ulcer by resection is violated. Since one of the things we wish to accomplish in cases of duodenal ulcer is to lower gastric acidity, if an enteroenterostomy is not performed between the long loops of jejunum anastomosed to the stomach, all the accumulated alkaline jejunal contents in the proximal loop of jejunum will be emptied into the stomach, thus neutralizing acidity. If, on the other hand, an enteroenterostomy is done between the proximal and distal loops of the jejunum, following antecolic or even retrocolic anastomosis to the stomach, most of the alkaline jejunal contents that would otherwise pass into the stomach enter the jejunum below it, and so its value of neutralization is lost. I shall now discuss a problem with which we have had considerable experience, namely duodenal diverticulum. We have had some heartaches in learning in which case to operate and in which not

to operate. Many duodenal diverticula undoubtedly do not produce symptoms of sufficient magnitude to justify operation. Occasional cases are encountered in which ulcerations occur, owing to erosion within the diverticulum, or distressing symptoms are present as a result of accumulations within the sac, as in the case shown in Figure 4. In this illustration may be seen the type of diverticulum that lends itself well to operation, and in Figure 5 is shown the type that presents a difficult operative problem. We have learned from experi-

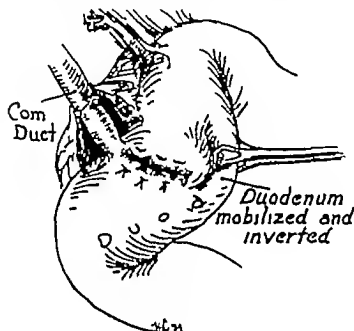

FIGURE 6. Removal of an External Safely Removable Duodenal Diverticulum

The duodenum has been mobilized and inverted and the diverticulum cut off and its neck inverted. Note the relation of the origin of the diverticulum to the point of entrance into the duodenum of the common bile duct. Care must be exercised lest inversion of the neck of the sac obstruct the common duct.

ence with these cases that the diverticula appearing on the outer wall usually have their origin behind the duodenum, but can be approached by mobilizing the duodenum and turning it inward. On the other hand, those diverticula projecting from the inner wall of the duodenum arise from the posterior wall and burrow into the head of the pancreas and into the vascular structures at the angle made by the curve of the duodenum to such an extent that they can be dissected only with the greatest difficulty and often, we believe, with an unjustifiable hazard.

Most duodenal diverticula, even though they appear on the outer wall of the duodenum, arise, as already stated, from the posterior aspect of the duodenum. It should be remembered that the point at which they arise is frequently adjacent to that point at which the common bile duct enters the duodenum. After the diverticulum has been cut off at its neck, one should be extremely careful that inversion of the diverticulum does not obstruct

the point of entrance of the common duct (Fig. 6).

Finally, I wish to present in outline a new operative procedure that may well prove useful to any one who has to deal with gastrojejunal ulcer, with gastrojejunocolic fistula or with carcinoma high in the jejunum. This operation I was forced to develop in order to deal with a carcinoma of the jejunum situated so high that its resection left an

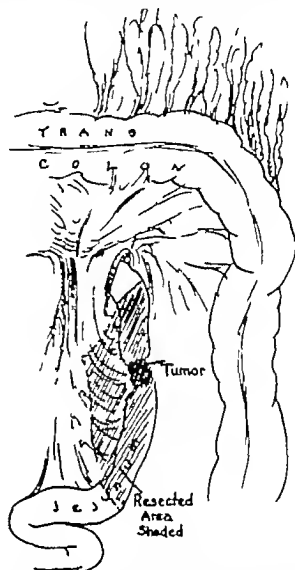

FIGURE 7. Resection of a High Jejunal Tumor

The shaded area of the jejunum distal and proximal to the tumor is to be removed together with the mesentery. Note the short stump of jejunum that will remain.

inadequate peritoneal stump of jejunum for end-to-end anastomosis.

As will be seen in Figure 7 following the removal of an adequate amount of jejunum for carcinoma there was but a small stump of jejunum at the ligament of Treitz, with too short a mesentery and an intraperitoneal portion to permit safe end-to-end anastomosis. Even had it been possible, the anastomosis would have retracted retroperitoneally beneath the vascular mesenteric root, so that there would have been the distinct possibility of obstruction from pressure and the danger of leakage.

After removal of the segment of high jejunum both ends of the jejunum were inverted and reinforced with interrupted silk stitches. The parietal

peritoneum about the upper short stump of jejunum at the ligament of Treitz was then incised, and the stump was pushed beneath the vascular mesenteric root until it was on the opposite side of

right side of the abdomen and then mobilizing the retroperitoneal duodenum has proved of distinct value. The procedure will, I am sure, prove useful for anyone who has to deal with these difficult high jejunal resections in the presence of a short jejunal stump.

As I listen to the discussions in symposiums such as this one, I am impressed with the progress which has been made, particularly in this field. In this as in so many other fields, it is strikingly evident that progress has been accomplished by united efforts rather than by the individual efforts of those interested in the special aspects of these conditions—gastroenterologists, physicians, surgeons, radiologists and anesthetists. In past years a discussion of the treatment of gastric and duodenal ulcers at any medical meeting was certain to bring

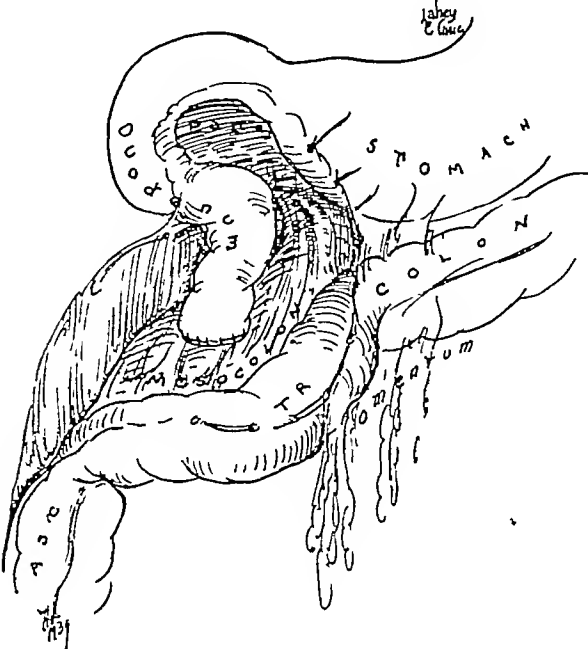

FIGURE 8 Resection of a High Jejunal Tumor

The end of the short proximal stump is safely inverted, the parietal peritoneum freed from it and the stump pushed beneath the mesenteric vessels onto the opposite side. The rent in the parietal peritoneum is then closed.

the mesentery. The incised ligament of Treitz was then closed and the entire right hepatic flexure was turned down by incising its outer leaf of peritoneum. This revealed the retroperitoneal duodenum and the mobilized upper stump of jejunum (Fig 8). When this had been done the mesentery of the retroperitoneal duodenum and jejunum was of sufficient length so that when the transverse colon was put back in place the mobilized duodenum and jejunum could be passed over and in front of the transverse colon, the lower stump of jejunum would be brought up in an antecolic position and a safe lateral anastomosis could be accomplished between the antecolic mobilized duodenum and the jejunum (Fig 9).

These technical procedures are well illustrated by the line drawings. This method has been of value also in cases of jejunal ulcer. When a jejunal ulcer occurs in a case of no-loop gastroenterostomy, the proximal loop of jejunum is so short after the segment of the jejunum containing the ulcer has been resected that safe end-to-end anastomosis cannot be done. In such cases, and in cases of gastro-jejuno-colic fistula, this plan of transposing the duodenal stump beneath the mesenteric root to the

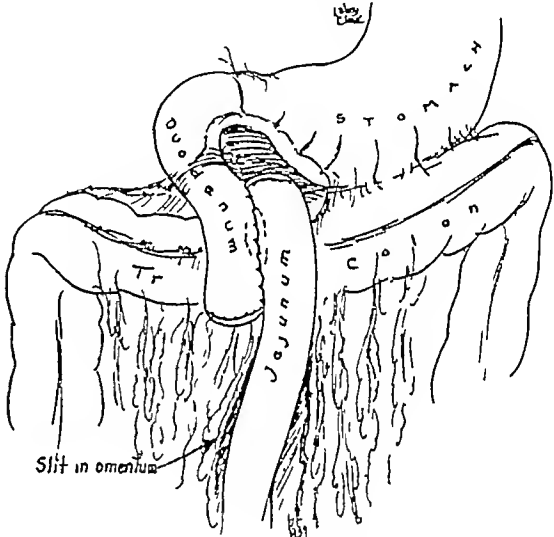

FIGURE 9 Resection of a High Jejunal Tumor

The hepatic flexure has been mobilized and turned down, and the retroperitoneal duodenum and transposed jejunal stump have been visualized and freed. The mobilized duodenum and jejunal stump are brought in front of the transverse colon after the hepatic flexure has been replaced. The lower stump of jejunum, with its end closed, is then brought in front of the transverse colon and a lateral antecolic duodenojejunal anastomosis made. Note that a slit is made in the fat omentum up to the transverse colon to permit the mesentery of the distal jejunal stump to fit into it snugly up to the transverse colon.

about acrimonious disputes between gastroenterologists and surgeons. It resulted undoubtedly in unjustifiable claims as to what could be accomplished by either method. Befogging partisanship undoubtedly produced unjustifiable prejudices which have now been largely overcome by this co-operation, for the benefit of the patient, to say nothing of the consciences of those who must manage them.

DISCUSSION OF PAPERS BY DRs. JONES, BENEDICT ALLEN
AND LAHEY

Dr. PHILEMON E. TRUESDALE, Fall River This has been an interesting and instructive group of papers. We have had presented a beacon light of knowledge in the fields of medicine and surgery. We have had the unusual pleasure of learning of the progress made with the gastroscope, which in the hands of men like Dr. Benedict has proved its diagnostic worth. Then we have listened to a discussion of treatment by leaders in surgery who not only indicated the pitfalls but also pointed out the best known methods for keeping the mortality low and rehabilitation high. The material as presented is evidence of the most advanced thought in dealing with certain types of cases which are often difficult and unpromising, and some times tragic.

My own interest in this subject dates back many years. In 1914 in the *Boston Medical and Surgical Journal* I published a report of 8 cases of pylorotomy for ulcer and quoted Dr. Rodman as having collected 31 cases from the work of five surgeons—Mayo, Robson, Clark, Finney and Rodman. In the latter series, there had been only 1 operative death—a somewhat startling figure.

My first case came entirely by chance. A man about fifty years of age came to the clinic with a history of stomach trouble for years. He had had an attack of abdominal pain and vomiting following a long period of digestive upsets. He had lost 10 to 15 pounds in weight in a few weeks and was quite emaciated. I could feel a mass in the upper abdomen to the right of the midline. The clinical, x-ray and operative diagnoses were cancer of the stomach. I decided to operate in two stages and did

a posterior gastroenterostomy first. After ten days, I removed the pyloric end of the stomach. It was amazing to observe that the inflammatory process which I had believed to be malignant was not more than half the size it was when observed in the first operation. Pathological examination of this specimen showed that it was ulcer not cancer. The man made a very satisfactory convalescence and was more comfortable than any patient on whom we had done a gastroenterostomy.

We did 7 similar operations for ulcer and published all 8 cases in 1914 as mentioned above. There was some doubt as to the extent of the operation being done at that time, and pylorotomy was thought to consist simply in removing the pyloric sphincter muscle or an ulcer that was near the pylorus. The method employed in those operations was a Billroth II now more generally termed "partial gastrectomy." When an ulcer has become cicatrized and fused with the head of the pancreas in a somewhat fixed inflammatory mass, the danger in separating the structures involved is considerable. I have lost 1 patient after an operation in the presence of these conditions, owing to an error of judgment in attempting the radical procedure.

In 91 cases of gastric resection our mortality at the clinic has been 3 per cent. We employ the method of posterior anastomosis. In some countries, as England the anterior operation is practiced. In France, Belgium and Germany the surgeons whom I talked with last autumn were doing posterior anastomoses. There are certain cases, as Dr. Allen has pointed out, which owing to age, local complications and circulatory changes, should not be operated on by any radical procedure.

peritoneum about the upper short stump of jejunum at the ligament of Treitz was then incised, and the stump was pushed beneath the vascular mesenteric root until it was on the opposite side of

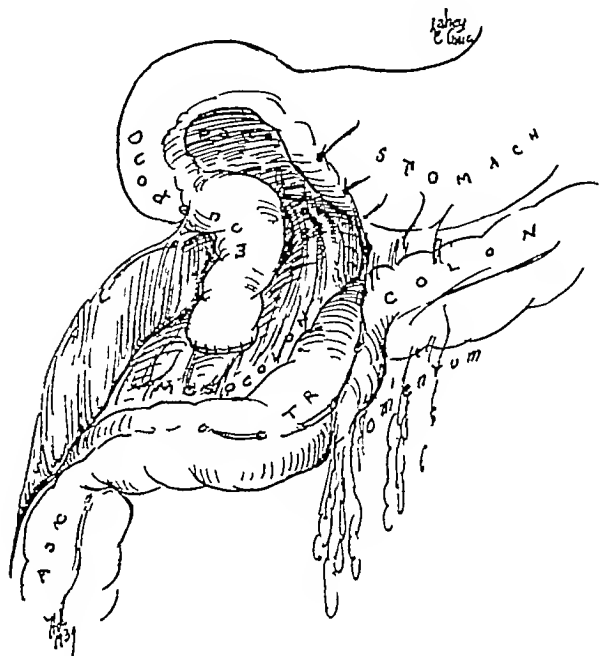

FIGURE 8 *Resection of a High Jejunal Tumor*

The end of the short proximal stump is safely inverted, the parietal peritoneum freed from it and the stump pushed beneath the mesenteric vessels onto the opposite side. The rent in the parietal peritoneum is then closed.

the mesentery. The incised ligament of Treitz was then closed and the entire right hepatic flexure was turned down by incising its outer leaf of peritoneum. This revealed the retroperitoneal duodenum and the mobilized upper stump of jejunum (Fig 8). When this had been done the mesentery of the retroperitoneal duodenum and jejunum was of sufficient length so that when the transverse colon was put back in place the mobilized duodenum and jejunum could be passed over and in front of the transverse colon, the lower stump of jejunum would be brought up in an antecolic position and a safe lateral anastomosis could be accomplished between the antecolic mobilized duodenum and the jejunum (Fig 9).

These technical procedures are well illustrated by the line drawings. This method has been of value also in cases of jejunal ulcer. When a jejunal ulcer occurs in a case of no-loop gastroenterostomy, the proximal loop of jejunum is so short after the segment of the jejunum containing the ulcer has been resected that safe end-to-end anastomosis cannot be done. In such cases, and in cases of gastro-jejuno-colic fistula, this plan of transposing the duodenal stump beneath the mesenteric root to the

right side of the abdomen and then mobilizing the retroperitoneal duodenum has proved of distinct value. The procedure will, I am sure, prove useful for anyone who has to deal with these difficult high jejunal resections in the presence of a short jejunal stump.

As I listen to the discussions in symposiums such as this one, I am impressed with the progress which has been made, particularly in this field. In this as in so many other fields, it is strikingly evident that progress has been accomplished by united efforts rather than by the individual efforts of those interested in the special aspects of these conditions—gastroenterologists, physicians, surgeons, radiologists and anesthetists. In past years a discussion of the treatment of gastric and duodenal ulcers at any medical meeting was certain to bring

about acrimonious disputes between gastroenterologists and surgeons. It resulted undoubtedly in unjustifiable claims as to what could be accomplished by either method. Befogging partisanship undoubtedly produced unjustifiable prejudices which have now been largely overcome by this co-operation, for the benefit of the patient, to say nothing of the consciences of those who must manage them.

least, before relapse occurs. Too long or too short courses of treatment, too many or too few shock reactions, discharge too soon after the disappearance of psychotic reactions, may have an untoward influence on the therapeutic result.⁴

Most authors report better results with insulin than with Metrazol in the treatment of schizophrenia, although some remissions have been effected with a combination of the two drugs.⁴ Certain patients who have shown no benefit from insulin have improved when Metrazol was administered, and vice versa. In some cases the production of convulsions, with either insulin or Metrazol, has seemed to be the requisite for improvement.

Continued investigation bears out certain general impressions in regard to criteria to be considered in judging the probability of favorable outcome from shock therapy. These criteria are as follows: the longer the duration of the psychosis before treatment is begun, the lower is the percentage of recovery and improvement, the paranoid and catatonic types respond better, on the whole, than do the hebephrenic and simple types; the personalities which have been comparatively well adjusted, with a minimum of schizoid characteristics, before the onset of the psychosis have the better prognosis. Little has been written stressing the importance of psychotherapy following remission, and it is necessary to keep in mind that resocialization directed toward establishing the most suitable environment for the individual, with its particular limitations in endowment, will be a major factor in withstanding relapse.

Insulin has been found to have little value in the treatment of affective disorders, while Metrazol has produced, at least temporarily, favorable results in a sufficient number of cases of manic depressive and involutional psychosis to merit attention. The literature contains relatively few reports, probably because the prognosis in affective psychoses is so much better than that in schizophrenia that a debatable kind of treatment is less warrantable and needful. Bennett⁶ reports excellent immediate results in a series of 10 cases, of which 6 were depressive psychoses and 4 were severe types of involutional psychosis.

Dangers of Shock Therapy

As the initial enthusiasm about shock therapy has waned, more attention has been given to the dangers involved in such drastic procedure. There have been an increased number of reports on the destructive effects of insulin and Metrazol on brain tissue. In fact, the seriousness of this untoward possibility is not a negligible consideration in attempting to evaluate the soundness of shock therapy. Dislocations of joints, fractures of the long

bones and crushing of vertebrae are admittedly disadvantages that accompany the Metrazol convulsions in a small percentage of cases. Proper nursing surveillance during treatment, and thorough examination before treatment in order to determine the presence or absence of bone disease, may in large part do away with such eventualities. Possible damage to the brain cells cannot, on the other hand, be guarded against with a comparable degree of certainty. A specific number of shock insults to the brain of one patient may result in no appreciable injury, while the same number of comas or convulsions may cause serious and irreparable damage to another. There are no reliable standards by which to judge how much treatment a patient may undergo without injury of serious proportions. Even though the patient may show clinical improvement or recovery following shock therapy, we do not know that future relapses may not be due, at least in part, to the traumatizing effect of the therapy itself.

Experiments with insulin and Metrazol on animals have resulted in injury to the brain cells, and the histopathologic changes have not always been limited to the cortex. Liebert and Weil,⁷ using Metrazol injections with rabbits, found in the autopsied brains shrinking of cytoplasm and nuclei of neurons, and hyperplasia and hypertrophy of different types of glia cells. These findings were more pronounced in the striatum and hippocampus than in the cerebral cortex. The degenerative effect of insulin on the brain cells of animals has been reviewed by Baker.⁸

In examining the brains of 5 schizophrenic patients who died during insulin shock treatment, Ferraro and Jervis⁹ found chromatolysis and glial proliferation in a majority of the cells of the cerebral cortex and proliferation of blood vessel cells, and frequently obliteration of the lumen.

The loss of memory for recently acquired skills and for recent events following Metrazol therapy has been observed by Ziskind and Somerfeld.¹⁰ One patient after twelve convulsions showed a persistent memory defect in that he forgot how to play Chinese checkers and how to keep score in badminton, both recently learned.

From a review of the literature and from a study of hypoglycemia in insulin shock in diabetic patients, hypoglycemia secondary to necrosis or functional overactivity of the islands of Langerhans, insulin shock therapy and experimental hypoglycemia in animals, Baker⁸ concludes "It seems very apparent that continued repeated hypoglycemia may definitely produce a depression of the cerebral function and even an irreversible degeneration of the brain tissue and cells, resulting in

long-continued or permanent functional damage or even death"

"TOTAL PUSH" IN SCHIZOPHRENIA

The problem of schizophrenia in its chronic manifestations has been attacked in another way, less drastic than pharmacological treatment and entirely without danger to the patient. Every psychiatrist knows that there is a tendency to consider that the hospitalized schizophrenic patient will remain sick or get well regardless of treatment, and that time and effort are wasted in attempting to influence the course of the disease. Myerson,¹¹ believing that the deterioration of the schizophrenic patient may be more superficial than it appears, and not necessarily dependent on unfathomable chemical and metabolic changes, devised the method of "total push." This is comprised of common-sense procedures directed toward more individual care for the patient, with the aim of increasing his self-respect and encouraging normal social interests. Particular attention is paid to diet and attractiveness in the service of meals, to clothing,—the old, ward bathrobe being discarded,—to tonsorial service, to exercise, play and other recreations and to psychotherapy.

There is nothing new in the therapeutic formula, except for the perseverance and strenuousness with which it is carried out. No claim is made as regards cure, but in the comparatively small groups in which the treatment has been instituted the incidence of death has decreased, discharges have increased and deterioration has often been replaced by more normal social behavior. Tillotson¹² reports similar results at the McLean Hospital in Belmont, Massachusetts. An interesting point in the "total push" method is that the inertia of the negativistic, resistant patient can often be broken down into voluntary activity by passive muscular movements carried on by the physical trainer.

ELECTROENCEPHALOGRAPHY

The electroencephalogram, an electrical record of the physiological activity of the cortex of the brain, has been proved of unquestionable value in helping to establish a diagnosis of certain organic lesions in the brain. However, the significance of abnormal waves is far from being completely understood. Whether or not abnormalities in the electroencephalogram indicate lesions in the brain, and to what extent physiological disturbance can be present without the presence of a definite lesion, are still to be determined. Recently there have been reports of electroencephalographic studies on psychotic patients. Davis and Davis¹³ have

found that although the electroencephalogram of a psychotic individual may not differ fundamentally in pattern from that of a normal person, as a group the psychotics show in their electroencephalograms a significantly larger percentage of abnormalities than does the normal group. In an investigation being carried on at present, Davis¹⁴ is studying the tracings of a large group of psychotic patients. Her results in patients who received pharmacological shock treatment are of particular interest. If the electroencephalographic patterns of such patients were normal before treatment, they became abnormal during and following its termination. Patterns that were abnormal before treatment remained so, and the abnormalities increased during and after treatment was concluded.

METABOLIC STUDIES IN PSYCHOSES

The theory or belief that psychotic illness is dependent on chemical or metabolic imbalance or dysfunction is given support by the careful and thorough investigations of Gjessing,^{15, 16} in Oslo. During the last thirteen or fourteen years he has studied intensively the metabolism of some 30 patients. Ten of these fell into the group exhibiting clear-cut periodic episodes of excitement or stupor. Gjessing's work shows that in each of these patients the episodes of excitement or stupor synchronize with a consistent rhythmic imbalance in nitrogen metabolism. In some cases it was found that nitrogen gradually accumulated in the body until a certain concentration was reached. At this point excretion began. With the onset of excretion the catatonic stupor or excitement developed. Gjessing points out that it is not the change in motor activity that can account for the change in the nitrogen balance, since in some cases the excitement or stupor did not begin until a day or two after nitrogen had begun to be excreted. In other cases the catatonic episode set in at the end of a period of nitrogen excretion and the stupor or excitement continued during an interval of nitrogen retention. Determinations of the nonprotein nitrogen of the blood also showed rhythmic curves, but in reverse manner to the nitrogen-balance curves.

Gjessing postulates the possibility that at the times of maximum retention or excretion toxic substances are formed which produce the excitement or stupor. He further found that a nitrogen balance could be effected and maintained by the administration of thyroxin. With this accomplished, the periodic episodes of excitement or stupor were prevented from recurring. A patient who had had stuporous phases every month for six or seven years continued month after month without re-

lapse after beginning the thyroid. Gjesing makes no pretension of cure in these selected cases of periodic catatonia, but states simply that a functional deficiency is compensated by the continued use of thyroxin. In some individuals their own thyroid glands seemed to have been influenced, so that relapses did not occur when the thyroid dosage was discontinued.

PSYCHOLOGICAL AND PSYCHOBIOLOGICAL STUDIES

One of the basic principles, and perhaps the most important principle, of present-day psychiatry is that mind and body are not separate. What is called the mind influences and is influenced by bodily reactions. There is no evidence that thoughts or ideas exist independent of physical structure, and their existence is dependent on physiological activity within the body. What might be called a corollary of this principle is that feelings or emotions are not simply ideas but are intimately bound up with bodily, physical reactions, and are responses to stimuli either within the body or within the organism's environment.

Practically, this means that a thought or a combination of ideas may be of enough significance to the individual to result in physiological reactions in various parts of the body. For the doctor, the significance of this is that he frequently sees patients who complain of physiological disturbances which arise, without comprehension on their part, from thoughts, situations, conflicts or frustrations. In some cases such physiological disturbances may eventually result in observable physical disease.

The fact that doctors do not know or fail to remember that emotions can cause physiological disturbance, means that many patients are not going to be given proper treatment. Many physicians still practice as though they thought that if no physical disease is present nothing is wrong with the patient except his imagination.

Considering the consequence of all this, the appearance of the new journal, *Psychosomatic Medicine* is most welcome. It is a quarterly publication, and contains articles on experimental and clinical studies. Up to the present the articles have not been forbiddingly technical. Psychological and physical factors are evaluated in the diseases studied. No prejudice is generally shown in favor of one school of psychiatric interpretation over another.

In a review by Brush¹⁷ of the literature relative to the psychiatric aspects of gastrointestinal disorders, Dr. Chester M. Jones, of the Massachusetts General Hospital, is quoted as saying, "It is of interest that more and more scrutiny is being directed toward the relationship between the central nervous system, the autonomic nervous system and

the digestive tract. The importance of the psyche in its influence on the digestive tract is being more clearly and logically presented." In studying 50 cases of bronchial asthma, McDermott and Cobb¹⁸ found that 37 per cent of the patients seemed to have an emotional component to their asthmatic attacks. Caughey,¹⁹ in a comprehensive analysis of the medical—not psychiatric—literature on cardiovascular occlusion, concludes that "in many patients the symptoms have been precipitated or perpetuated by faulty medical supervision of the difficult problems involved."

Psychosomatic Medicine should make valuable reading for the physician who wants to add to his knowledge of psychological factors in the various disease entities.

Group psychotherapy has been practiced with a good measure of success for many years. One such venture was instituted by Dr. Joseph H. Pratt at the Boston Dispensary, and has continued year after year as a "thought-control" class.²⁰ The milder neurotic reactions have been dealt with in this clinic, principally with the methods of persuasion and suggestion. In 1935 Schilder,²¹ at the Bellevue Hospital in New York City, began group psychotherapy with the more severe neuroses. Psychoanalytical concepts are used. One criticism of psychoanalytical therapy has always been that comparatively few patients can be treated because of the great amount of time required for each analysis. By group therapy Schilder is able to treat a relatively large number of patients, working with seven or eight at a time. An advantage of group therapy is the feeling of security and relief for the individual in finding that he is not alone in having thoughts and impulses which have seemed to him to isolate him from society. During a visit to this clinic it was interesting to observe the freedom with which the patients gave expression to the most personal thoughts and phantasies. Schilder's method of group psychotherapy is described in some detail in his book, *Psychotherapy*.²²

Considering the intricacies and the involved structures often found in the formulations of psychoanalytical theories and concepts of human motivation, it is worthy of note that such comparatively simple conclusions as the following examples came out of certain of Schilder's group discussions:

Human beings should gladly acknowledge their shortcomings. They should be taught neither to overcompensate for them nor to brush them out of consciousness. The ideal of general efficiency and of striving to be blameless is a wrong one. There is no reason to believe that there is only one fundamental problem lying at the base of neuroses. Modern men suffer from the idea that they should be per-

fect. Parents have to pay dearly for every perfectionistic ideal they put into their children's minds.²¹

Such conclusions are found in the common-sense foundations of any good "school" of psychotherapy.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26111

PRESENTATION OF CASE

A fifty-six year-old American schoolteacher was admitted complaining of dyspnea on exertion.

Five years before entry on returning from a trip to Europe and while carrying heavy suitcases he had an acute attack of pain over the heart and colon lasting for four hours. After his return home he had a recurrence of this pain and fainted. He was kept in bed for four or five days. Previous to this attack he had had no period of ill health. Up to seven years before entry he had been very active and had had no difficulty in climbing mountains. At this time, however, he noticed some fatigue, and mountain climbing was discontinued. Three years before coming to the hospital his fatigability increased to such an extent that he was unable to walk and was compelled to give up playing the cello. Dyspnea on effort was rather variable and much less at some times than at others. When first seen by his physician four months before admission he was able to walk slowly on level ground. Three months prior to entry he had had a severe attack of breathlessness while attempting to put on automobile tire chains. He was compelled to lie down for relief and almost fainted. There was some pain and swelling of the left lower leg. He had been forced to give up work for a time, but six weeks later he felt better although there was still some pain in the left leg which varied in intensity. The left lower leg and foot were slightly edematous and cyanotic. A month before admission he had had a severe cold and subsequently had recurrent attacks of nausea and vomiting. Dyspnea and fatigue progressed rapidly, but the patient remained in bed for only one day before coming to the hospital. He had been taking varying amounts of digitalis during his entire illness.

Physical examination showed a tall, very thin man with marked arcus senilis. There was considerable cyanosis, with marked engorgement of the veins of the neck. The heart was moderately enlarged. The sounds were regular and of poor quality. A loud click was heard at the apex in mid-diastole. A reduplicated pulmonic second sound was heard in the recumbent position, and there

was a slight basal systolic murmur. The blood pressure was 120 systolic, 90 diastolic. The radial arteries were soft. A few rales were heard at both bases, and the liver edge could be readily palpated. There was slight edema of the ankles. No further details were noted.

The temperature was 98.0°F., the pulse 70, and the respirations 26.

Examination of the urine showed a specific gravity of 1.032, with a large trace of albumin. The sediment contained an occasional white blood cell and red blood cell and many finely granular and hyaline casts. The blood showed a red-cell count of 5,700,000, with a hemoglobin of 95 per cent. The white-cell count was 4800, with 74 per cent polymorphonuclears. An electrocardiogram showed a normal rhythm at a rate of 84, with a PR interval of 0.18 second. There was evidence of right bundle-branch block and low voltage of the QRS complexes. QRS₁ showed the major deflection inverted and T₁ was upright.

Shortly after entry another examination showed diminution in cyanosis and disappearance of the neck vein engorgement and basal rales. Two days after entry cyanosis of the head and extremities became marked and the neck veins were again distended. The liver extended to the umbilicus, and slight sacral edema was noted. The heart sounds were poor in quality and there was gallop rhythm. The symptoms were somewhat relieved by intravenous Mercupurin, and his condition exhibited no great change until early in the morning of the fifth hospital day, when he had an attack of dyspnea and cyanosis, became pulseless and collapsed. The blood pressure was 80 systolic, 30 diastolic. There was no complaint of pain, but the patient appeared to be in shock. He was placed in an oxygen tent and died five hours after the onset of this attack.

DIFFERENTIAL DIAGNOSIS

DR. EDWARD F. BLAND. I am impressed by the prominence of dyspnea throughout this patient's illness, extending over at least five years and possibly seven—dyspnea associated with fatigue. I am uncertain how much reliance we should put on the symptom of fatigue but I am impressed by the dyspnea. The facts that it was somewhat variable, that it sharply limited the patient to the extent that he led an inactive life for a number of years and that it lasted so long impress me considerably. It became more pronounced toward the end at which time there appeared a considerable degree of cyanosis, mentioned several times, and one or two recurring episodes of breathlessness with very little to be found in the lungs to

indicate acute pulmonary congestion. There is probably no single episode mentioned here that could be strictly considered typical of cardiac asthma. In addition to this cyanosis, there were also the prominently swollen neck veins. This venous congestion varied somewhat but remained an outstanding sign associated with another sign of serious heart weakness, namely a gallop rhythm and supporting evidence in the electrocardiogram of strain on the right side of the heart. I think, however, that we should be cautious in reading too much into this electrocardiogram for two reasons: low voltage was present which tends to make an estimation of axis deviation somewhat less reliable, and the presence of intraventricular block of the right bundle-branch type, although often associated with conditions that cause strain primarily on the right side of the heart, is, since it is fundamentally a conduction defect, more often the result of coronary arterial disease.

Furthermore, we cannot quite ignore the attack of severe pain five years before the patient's death, which recurred only once shortly thereafter. However, if this patient's subsequent incapacity represented the effects of slowly progressive coronary disease, and if this original attack of pain represented coronary occlusion, it would be most unusual to have this later limitation of reserve entirely manifested by dyspnea for five years and no anginal symptoms. I suggest that this one and only painful episode may have been due to pulmonary infarction. Throughout the illness, so far as the physical examination is concerned, there is a relative absence of evidence of pulmonary congestion. During this one spell of acute breathlessness, the patient preferred to lie down. That is most unusual with acute pulmonary congestion from left ventricular failure. Finally, toward the end of this patient's illness and at the time of the acute attack of breathlessness, evidence of phlebitis was observed.

It seems to me the differential diagnosis here lies between arteriosclerotic coronary disease and cor pulmonale, the latter secondary to recurring emboli to the lungs. Dr J H Means had a somewhat similar case a number of years ago. There was another, which I happened to have observed on the wards here, that was mistaken clinically for coronary disease, but when we knew the final answer, the heart failure of the right-sided type was entirely explained by recurring showers of small emboli, probably over a period of several years, with relatively few physical signs of such in the lungs.

There is no mention of the Hinton test in the record and no clinical indication of syphilis, there-

fore, I believe we can safely dismiss syphilis without further comment. Furthermore, there is no evidence of valvular disease, and no hypertension. It is difficult, however, to discard completely the idea that there may have been some underlying coronary insufficiency responsible for this patient's heart failure. Yet I am inclined to minimize it, considering the long duration of the symptoms in the absence of anginal pain and pulmonary congestion. The symptom of fatigue disturbs me a little. I cannot quite interpret that, but I see no reason to introduce into the discussion such unlikely possibilities as Simmond's disease or myasthenia gravis.

In conclusion I suspect that this patient had chronic cor pulmonale, with right-sided heart failure probably secondary to recurring small pulmonary emboli, and that he also had a thrombophlebitis in the left leg. Whether he had in addition some underlying coronary disease I should like to leave open, but I doubt if it was a factor of prime importance in his fatal illness. I think it would have been of some help in the differential diagnosis if we knew what the x-ray films showed. The patient lived only five days in the hospital, and I assume he was too sick during this time for such study. They might have given additional information as regards the shape of the pulmonary conus or the appearance of the hilus shadows.

DR HOWARD B SPRAGUE. The hilus shadows were very much increased, and under the fluoroscope there was a question in my mind about pulsation of the hilus shadow, which I think would support your diagnosis.

DR TRACY B MALLORY. Would you care to make any further comment, Dr Sprague?

DR SPRAGUE. Only that I think Dr Bland has done extremely well with this case. I was influenced toward a diagnosis of coronary disease by the history, which went back long before any appearance of phlebitis, and also by the bundle branch block. I think it teaches us that axis deviation and bundle-branch block ought to be considered together, the former may be the early stage of the latter.

DR PAUL D WHITE. How much bundle-branch block was there? Was it of an indeterminate degree? Did it look like coronary disease by the electrocardiogram?

DR SPRAGUE. It was a definite right bundle branch block. Do you think there is a type of bundle-branch block characteristic of coronary disease?

DR WHITE. There are various degrees of bundle

branch block. We ordinarily ascribe duration of the QRS waves beyond 0.12 second—that is, obvious bundle-branch block—to coronary disease.

Dr. SPRAGUE I should say that the QRS wave was wider than 0.12 second, and therefore characteristic of a fully developed bundle-branch block.

Dr. WHITE The extreme cyanosis at the end suggests pulmonary embolism.

Dr. SPRAGUE In the last coronary case of mine autopsied here I made a diagnosis of pulmonary embolism because of the extreme degree of cyanosis in the terminal attack, but no pulmonary embolism was found.

CLINICAL DIAGNOSES

Coronary heart disease (old infarct and possibly a new one)
Right bundle-branch block

Dr. BLAND'S DIAGNOSES

Chronic cor pulmonale.
Right-sided heart failure.
Recurrent pulmonary emboli.
Thrombophlebitis, left leg
Coronary disease?

ANATOMICAL DIAGNOSES

Pulmonary embolism and thrombosis, bilateral, multiple.
Thrombophlebitis, right popliteal
Mural thrombus, right auricular appendage.
Cardiac hypertrophy, arteriosclerotic type
Passive congestion of liver, spleen and kidney
Thrombosis of hemorrhoidal vessels
Arteriosclerosis, moderate, coronary, aortic and pulmonary
Central necrosis of liver
Pleuritis, chronic fibrous, right.
Ascites, slight.

PATHOLOGICAL DISCUSSION

Dr. MALLORY At the time of autopsy we found a markedly dilated right auricle and ventricle, and in spite of this dilatation the right ventricle was thicker than normal, measuring 5 mm. The pulmonary artery was completely filled with thrombotic masses, and with a little investigation it was clear that the thrombus on the left was old, completely organized and evidently had been present for a long period of time, whereas that on the right was quite fresh and represented without much question a terminal episode. There was no infarction of either lung, despite the almost com-

plete occlusion of the pulmonary tree. The coronary arteries were essentially negative.

Dr. BLAND Were the thrombi formed *in situ* or were they secondary?

Dr. MALLORY It is almost impossible to give a definite answer on that. By all odds the most probable thing to my mind, is an embolus followed by retrograde propagation of the clot to form a thrombus which eventually occluded the main artery, the whole process developing so slowly that time was permitted for collateral circulation to develop and prevent infarction.

Dr. J. H. MEANS The case we published with thrombus and occlusion of the pulmonary artery had marked dilatation of the bronchial artery. Was that the case here?

Dr. MALLORY It was not noted.

Dr. WHITE It is possible that right bundle branch block of lesser grades may be ascribed to marked dilatation of the right ventricle, but if so, such cases must be rare. Unless careful dissection is made of the bundle branches we cannot be sure that there is not an associated independent involvement of these branches, even without diffuse coronary sclerosis or the usual larger myocardial infarcts.

CASE 26112

PRESENTATION OF CASE

A fifty-two-year-old Italian janitor was admitted to the hospital complaining of swelling of the abdomen.

The patient had always been strong and healthy until three years before entry. At that time he became troubled with recurrent nosebleeds, which were frequently quite severe and required medical attention. He continued with this work however and was not otherwise troubled until a year and a half prior to admission, when he began to have morning nausea and noted an icteric tint to his skin. He was examined in the Out Patient Department and found to have an enlarged liver. The urine contained bile on this occasion and a blood Hinton test was positive. A Wassermann test of the blood was negative, however and repeated Hinton tests were negative. A year before coming to the hospital the jaundice became more pronounced and swelling of the ankles and abdomen was noted. His appetite became poor and weakness was noted. There was occasional vomiting and frequent frontal headaches. Weakness was progressive, and the patient was compelled to discontinue his work. Six months before entry he became distressed by itching of the legs but his

abdominal swelling became less following medication prescribed by a physician. Subsequently he felt better, but six days preceding entry he developed generalized aches and pains while on a trip in an open automobile. He returned home and had a severe chill lasting for an hour. This was followed by profuse perspiration, fever and increased abdominal girth. Despite these symptoms he went to a picnic and shortly after returning home felt chilly and developed a constant dull aching pain in his abdomen and back. These symptoms were partially relieved by powders administered by a physician, but admission was advised. There were no other symptoms of significance.

The patient had had smallpox at the age of nineteen months and typhoid fever two years later. He had always been a heavy drinker.

Physical examination showed a well-developed but poorly nourished, icteric, man who appeared quite ill. Oral hygiene was very poor, the tongue was dry and the breath fetid. There were impaired resonance, diminished breath sounds and crackling rales at both lung bases posteriorly. The apex of the heart was percussed to 11.5 cm from the midsternal line. The sounds were regular and of good quality, and a systolic murmur was audible at the apex. The blood pressure was 130 systolic, 75 diastolic. Liver dullness extended from the third right interspace to the costal margin, but no edge was felt. The abdomen was tense and distended, and there was shifting dullness in the flanks. Many large dilated subcutaneous veins were noted over the abdomen. There was no edema of the extremities.

The temperature was 100.0°F, the pulse 120, and the respirations 25.

Examination of the urine showed a specific gravity of 1.026, with a moderate amount of bile. The sediment contained 10 white blood cells per high-power field but was otherwise negative. The blood showed a red-cell count of 4,000,000, with a hemoglobin of 70 per cent. The white-cell count was 24,900, with 86 per cent polymorphonuclears. The van den Bergh showed 10.8 mg per 100 cc of bilirubin, with a direct reaction.

On the day following entry an abdominal paracentesis produced 3500 cc of bile-stained fluid with a specific gravity of 1.011 and a total protein of 3.6 gm per 100 cc. A cell count showed 2500 red blood cells and 15,800 white cells per cubic millimeter. Histological study showed lymphocytes predominating with moderate numbers of monocytes and polymorphonuclears, no tumor cells were seen. Following the tap the lower end of

the spleen was palpated. The patient became irrational, and his condition critical. On the third hospital day another abdominal tap produced 3100 cc with similar characteristics to those noted previously. Subsequently his condition became rapidly worse, and he died on the fourth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. HOWARD C. COGGESHALL. The history indicates that liver disease had been present for at least one and a half years prior to entry, because on examination in the Out Patient Department it is stated that his liver was enlarged. Bile was found in the urine, and an icteric tint was noted in the skin. For one and a half years prior to this examination the patient had been well except for recurrent nosebleeds. The past history is apparently negative except for the fact that he was a heavy drinker. Thus far it is apparent that the patient was suffering from some chronic disease of the liver which had been insidiously progressing until admission. One and a half years prior to entry the first evidence of real liver damage appeared, with jaundice, an enlarged liver and nausea. Six months later, definite signs of portal obstruction had developed, as evidenced by the abdominal swelling. He also had edema of the legs, which I assume was secondary to the ascites. He complained of itching of the legs, which could be explained either on the basis of chronic jaundice or subcutaneous edema. He was given some type of medication which reduced the abdominal swelling. This I assume to have been a mercurial diuretic. The terminal episode which brought him to the hospital was some type of intercurrent infection, probably bronchial pneumonia, possibly peritonitis. The results of the examination of the peritoneal fluid were more consistent with the characteristics of a transudate than with those of an exudate as discussed below. This rules out peritonitis, except for the tuberculous and syphilitic types, both of which are said to be occasionally responsible for terminal infections in portal cirrhosis of the liver.

Physical examination at the time of entry showed a fetid breath, crackling rales at both lung bases posteriorly, increased liver dullness, ascites, caput Medusae, a temperature of 100.0°F and a pulse of 120. Laboratory data showed bile in the urine with good ability to concentrate urine to 1.026, and a moderate anemia — 4,000,000 red blood cells, with 70 per cent hemoglobin. There was a marked leukocytosis, with 24,900 leukocytes, 86 per cent of which were polymorphonuclears. A van den Bergh test was distinctly elevated, with 10.8 mg per 100 cc of bilirubin. A paracentesis yielded 3500 cc.

of bile-stained fluid, having a specific gravity of 1.011, with a total protein of 3.6 gm per 100 cc. The leukocyte count on this fluid was slightly elevated, — 15,800 cells per cubic millimeter, — with a predominance of lymphocytes. The interpretation of this fluid is difficult because its specific gravity of 1.011 is inconsistent with a total protein of 3.6 gm per 100 cc. Theoretically, a specific gravity of 1.010 indicates that there is about 1 gm per 100 cc. of total protein present. It is apparent that the specific gravity is either too low or the total protein is too high. In cirrhosis of the liver, the total protein is usually 0.8 to 0.9 gm per 100 cc. and in heart failure, it may range from 0.8 to 4.6 gm. The value of nearly 4 gm in this fluid is distinctly higher than one would expect for ascites secondary to cirrhosis of the liver. One might explain this increase of protein if one were sure that he had had either mercurial diuretics or digitalis immediately prior to entry, because it is known that removal of ascitic and pleural fluids by diuretics will concentrate the protein. About all one can say about this fluid is that it is not the type of fluid usually found with cirrhosis of the liver. There is also evidence of some inflammatory reaction, as shown by the leukocyte count, but this apparently was a sterile fluid, because of the low percentage of polymorphonuclear leukocytes. Such a reaction might be explained by thrombosis of the splenic or mesenteric veins.

The diagnosis of this case has to be made mostly on the basis of the history, which seems to be most consistent with portal cirrhosis. The chief inconsistency with this diagnosis is the presence of jaundice for one and a half years, but from the history it is difficult to be sure whether it was present continuously or intermittently. Ascites rather than jaundice is the commonest symptom of portal cirrhosis. Biliary cirrhosis usually occurs in young people and jaundice is the predominant symptom. There is no history of pain, fever or acute attacks of pain associated with jaundice. One might think of syphilitic cirrhosis, but in spite of the one positive Hinton test the repeated negative tests tend to rule out this possibility. The absence of serological evidence of syphilis does not rule out syphilitic cirrhosis, and in this case the clinical findings are consistent with this diagnosis; however, I do not believe one is justified in making this diagnosis when both the history and physical signs fail to give other evidence of syphilis. The possibility of splenic vein thrombosis should be considered. However the spleen was not palpable at any time except after paracentesis and one would expect a greater degree of anemia. Various types of cancer are ruled out on the basis of the three-year history. There is little to go with a

diagnosis of lymphoma except for the large liver and spleen.

CLINICAL DIAGNOSES

Cirrhosis of liver
Cholemia
Neoplasm?
Hypertensive arteriosclerotic heart disease.

DR. COGGESHALL'S DIAGNOSES

Portal cirrhosis of liver
Hepatomegaly and splenomegaly
Ascites
Bronchopneumonia

ANATOMICAL DIAGNOSES

Cirrhosis of liver probably alcoholic
Peritonitis acute generalized (*Streptococcus haemolyticus*)
Subdiaphragmatic abscess
Esophageal varices
Jaundice
Perisplenitis, acute and chronic.
Ascites.
Pleuritis chronic fibrous.
Arteriosclerosis, aortic and coronary, very slight
Cardiac hypertrophy

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. The diagnosis of cirrhosis of the liver in this patient was fairly obvious and was of course made at the time of his entry on the wards. I am sure, however, that his rapid downhill course — he died within four days — was a great surprise to everyone. There is nothing in the initial physical examination or the note of the visiting man on his first day in the hospital to indicate that he was considered to be in a critical condition. By the next day, however, it was obvious that there must be some important complication. On the wards an acute atrophy of liver superimposed on the chronic cirrhosis was suspected. Dr. Coggeshall seriously considered a mesenteric thrombosis. There was nothing in the history or physical examination to give any precise lead although in retrospect after the autopsy the shaking chill of a few days before looms in imagination.

At postmortem examination a generalized peritonitis was found, from which beta hemolytic streptococci were grown in pure culture. The general peritonitis was evidently of very short duration, probably only one or two days old, but in the left upper quadrant beneath the diaphragm was a large fairly well encapsulated pocket of thick

pus, which must have been present for several days and probably antedated his entrance to the hospital. The rupture of this subdiaphragmatic abscess into the general peritoneal cavity probably occurred subsequent to the abdominal paracenteses.

The liver was normal in size, weighing 1800 gm, but was finely nodular, very firm and fibrotic. It was typical of a chronic alcoholic cirrhosis. The spleen was quite markedly enlarged, weighing 750 gm, and showed a slight diffuse fibrosis. There were well-marked esophageal varices. The heart was slightly hypertrophied, weighing 400 gm, and the coronary arteries showed rare atheromatous plaques, without narrowing of the lumens.

Erratum

In copy editing "Case 26072" (*New Eng J Med* 222:274-276, 1940), certain changes were made in the text which altered the meaning of Dr Michelsen's discussion. The following words, as they appeared in the original copy, should be substituted on page 275:

First column, lines 44 and 45 for "cerebral control of the fibers" substitute "cerebral control and inhibitions"

Second column, line 29 for "such a lesion," substitute "an intramedullary lesion"

Second column, line 31 for "intradural," substitute "intramedullary"

Second column, lines 36 and 37 for "correct, inasmuch as a," substitute "correct. [Paragraph] This objection based upon the history applies to all intradural tumors. A."

THE HEALTH OF THE NATION

A RECENT interval after the beginning of the new year having been allowed for the discussion of the State of the Nation," we may now turn our attention with propriety to the Health of the Nation." On January 7 the United States Public Health Service released fourteen mimeographed pages having to do largely with vital statistics for the year 1938, in comparison with preceding years and with parts of 1939, and interspersed with comments and quotations. The general tendency toward lower mortality rates continues, the provisional rate for 1938 being 10.6 per 1000 as compared with 11.2 for 1937. The lowest prior mortality rate ever recorded was that of 10.7 for 1933. Typhoid fever, scarlet fever, diphtheria, poliomyelitis, epidemic meningitis, tuberculosis, diseases of pregnancy and childbirth and several other causes showed the lowest death rates on

record. At the same time there is occurring a rapid expansion of public health bureaus and services. The number of counties employing full time health officers reached an all-time high of 1371, while approximately 1500 persons received public health training for positions in official agencies during the year.

Of the many groups that are striving to promote their special interests, the mental hygienists may take great satisfaction and comfort in the statement that Dr. Parran believes that mental and nervous diseases and epilepsy together represent the largest unsolved problem in medicine." There is no lack of recognition of other problems, however, for cancer, venereal disease and "rheumatism,"—there being an estimated total of nearly 7,000,000 cases of the last,—as well as such geriatric diseases as arteriosclerosis, hypertension and heart disease, are recognized as continuing, and often increasing, phenomena among our people. The work of the marine hospitals has increased, less it appears for the merchant seamen than for veterans and patients of the Works Progress Administration.

Current changes in what used to be the primary and picturesque function of the United States Public Health Service are of interest. The quarantine and immigration activities no longer have that salty flavor associated with rope ladders and seagoing doctors. To be sure quarantine officers inspected 15,525 vessels during 1938, but the present commentator will be blown if a lot of it was not done on dry land! It was bad enough when the old steam tugs were replaced by Diesel motored craft at that misty offshore anchorage called quarantine. There is no longer time for a friendly glass in the pilot house before getting on with the business, the ships proceed directly to their docks with nothing more substantial than wireless permission to do so. They call it "radio pratique," but to many an old-time sailor it must seem like going without his breakfast. During the past fiscal year, 1878 airplanes, carrying 25,842 passengers, were inspected.

The glaring item of the report concerns smallpox. If there is any disease for the prevention and eradication of which we have a formula, that

disease is smallpox. Yet its incidence has been increasing in this country for the past ten years. The 14,939 reported cases in 1938 were nearly twice the number represented by the 1933-37 median. Perhaps had Edward Jenner spent his time on syphilis it would have been more effective.

VIGGO CHRISTIANSEN

VIGGO CHRISTIANSEN, founder of Danish neurology and president of the Third International Neurological Congress held in Copenhagen in August, 1939, died in Copenhagen, November 3. Son of an officer in the Danish Navy, he received his medical degree in 1895 and his doctor's degree in 1898. As is usual in Denmark, his final degree was accompanied by the publication of his thesis, *Om Urinens Giftighed specielt hos Sindssyge* (*The Toxicity of Urine, Especially in the Insane*), a volume of 457 pages, Copenhagen, 1898.

He soon was attracted to neurology, then not recognized in Denmark as a specialty, and in 1901 succeeded in forming a small department in the *Kommunehospitalet*. In 1907 he opened a private clinic for patients with neurological diseases. Many years elapsed, however, before neurology became firmly established in Copenhagen, for it was not until long after the World War, in 1929, that a department was set up in the *Rigshospitalet*, with Christiansen in charge. In 1934 he added a department of neurosurgery. Resigning from the hospital in 1938, he was followed by Professor Mogens Fog, as head of the department of neurology. Christiansen was connected with the University of Copenhagen all during his active life.

He was a member of numerous Danish and foreign medical societies, including correspondent membership in the *Académie de Médecin de Paris* and honorary membership in the Royal Society of Medicine of London. He had lectured at the universities of Paris, Strassbourg, Lyon and Reykjavik. Christiansen was an honorary member of the First International Neurological Congress in Berne in 1931 and vice-president of the Second Congress in London in 1933. In addition he had served on the board of editors of many scientific journals

and was Danish editor for the *Nordisk tidsskrift for retsmedicin-psykiatri*.

His best known publications were *Kliniske forelæsninger over nervesygdomme* (Copenhagen, 1905) and *Les tumeurs du cerveau* (Paris, 1921).

At the Copenhagen congress one saw an elderly man, cigarette in lips, walking the rotunda of the meeting hall like a fleet commander, small, alert and cordial, but with an air of the navy in both his manner and his gait. A pioneer and a founder of a school, now the center of advanced research, Christiansen will long be remembered in the history of neurology.

MEDICAL EPONYM

BIER'S HYPEREMIA

August Bier, then first assistant physician at the surgical clinic of the University of Kiel, first described his use of artificial hyperemia in the treatment of disease in the *Festschrift* (Kiel and Leipzig: Lipsius & Tischer, 1893) in honor of Friedrich von Esmarch's seventieth birthday. This contribution is entitled "Behandlung chirurgischer Tuberkulose der Gliedmaassen mit Stauungshyperämie [The Treatment of Surgical Tuberculosis of the Extremities by Congestive Hyperemia]." The translation of a portion of the article is as follows:

My first experiments with arterial hyperemia were begun in August, 1891, in the following manner. A hole was cut in a simple wooden box large enough so that the tuberculous limb could be placed inside. The extremity was suspended in a sling, the ends of which ran through two holes in the cover of the box and were tied outside so that the limb hung free. The box was heated by means of a spirit lamp like a Quincke's sweat bed, and the air brought to a temperature of 70 to 100°C. The desired effect on the blood circulation was attained in a most satisfactory manner.

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., *Secretary*
330 Dartmouth Street
Boston

SEPSIS FOLLOWING POSTPARTUM HEMORRHAGE

Mrs. E. W., a thirty-two-year-old para VIII, entered the hospital January 9, 1934, in labor at term.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

The family history was not obtained. The past history was uneventful except for pneumonia at the age of thirty. She had had five normal full term deliveries and two premature labors. Catamenia were regular, with a twenty-eight-day cycle. The last menstruation had started March 24, 1933, making the expected date of confinement December 31. She had had no antepartum care, but the pregnancy had been normal so far as she knew except for slight swelling of the ankles.

Examination on admission showed a well developed woman, whose color and appearance were good. The temperature was $99.2^{\circ}\text{F}.$, the pulse 108, and the blood pressure 110 systolic, 78 diastolic. The heart sounds were clear and regular, and there were no murmurs. The lungs showed uniform resonance and clear respiration. There was slight edema of the lower extremities. Urine examination was essentially negative. On abdominal palpation the fetal head was located at the fundus, with the small parts on the left. Rectal examination revealed a frank breech presentation and the os two fingers dilated. The fetal heart sounds were clear and regular, the rate being 140. The external pelvic measurements were essentially normal.

Labor progressed slowly after an early rupture of the membranes. During this time the temperature rose to 101.6°F but fell to 98.4 before delivery.

At 8.30 a.m. on January 14 the os was fully dilated. Signs of fetal distress were present in the form of irregularity of the heart sounds. The patient was therefore delivered under full surgical anesthesia, a manual extraction of the breech, converted to a footling, being done without great difficulty. The baby was stillborn and all attempts at resuscitation failed. The placenta was expressed in fifteen minutes, but the uterus reacted poorly in spite of pituitary extract, ergot, massage and ice. The cervix was then exposed and a deep tear found on the left, but as the bleeding was obviously coming from a relaxed fundus, it was deemed advisable not to repair the cervix but to pack the uterus at once. The uterus was therefore tightly packed with a three yard strip, which appeared to control the bleeding. Since the patient's pulse was weak and thready she was transfused with 650 cc. of citrated blood and put to bed in shock position, heaters and blankets being applied. She improved rapidly. The pack was removed the following day, and there was no further hemorrhage.

The temperature, however, rose to 102.4°F within twelve hours after delivery and remained elevated, with occasional intermissions, reaching the maximum of 105.0° on the ninth day. The pulse

varied from 110 to 130. The white-cell count was 16,500 on the fourth day, and 34,000 on the ninth.

A pelvic examination on the ninth day showed the uterus large and slightly tender. The left vault was slightly tender, and the left sided tear of the cervix was plainly felt. The finger was passed through the internal os, and on withdrawal followed by a gush of foul lochia.

The patient was kept in Fowler's position from the second day until the temperature fell to approximately normal. Ice was applied to the fundus, and several courses of fluid extract of ergot by mouth were given.

From the peak of 105.0°F on the ninth day, the temperature fell gradually, but was slightly elevated until the twenty-fifth postpartum day.

The patient was discharged on the twenty-seventh postpartum day. Discharge examination showed the uterus in good position and well involuted, the cervix deeply lacerated on the left side, and no masses or tenderness in the vaginal vaults.

Comment. This case of infection following a postpartum hemorrhage occurred in a multipara whose delivery was complicated by a breech extraction and by uterine packing. It is very difficult to say that the infection was dependent on either of these procedures because the temperature was elevated before delivery. On the other hand, it is not possible to say that infection already existed because of one temperature rise. It is quite likely that the tear of the cervix resulted directly from the breech delivery, properly undertaken but unduly hastened because of the irregular fetal heart. The postpartum hemorrhage was uterine solely as the exposed cervix proved. No cultures were taken from either the uterus or the blood stream, but the chart and history were perfectly characteristic of uterine sepsis. Conservatism was followed throughout, the uterus being left scrupulously alone after the packing had been removed. It must be borne in mind that packing of the uterus is always a potential factor in uterine sepsis, but because of this one should not be deterred from packing in the face of actual hemorrhage. It is better to pack a uterus and treat sepsis than to allow a patient to become exsanguinated.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions of the Medical Postgraduate Extension Courses have been arranged for the week beginning March 17

BERKSHIRE

Thursday March 21 at 4.30 p.m., at the Bishop House of Mercy Hospital Pittsfield. Syphilis in Pregnancy and the Offspring. Instructor Rudolph Jacoby. Harry G. Mellen, Chairman.

disease is smallpox. Yet its incidence has been increasing in this country for the past ten years. The 14,939 reported cases in 1938 were nearly twice the number represented by the 1933-37 median. Perhaps had Edward Jenner spent his time on syphilis it would have been more effective.

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., *Secretary*
330 Dartmouth Street
Boston

SEPSIS FOLLOWING POSTPARTUM HEMORRHAGE

Mrs. E. W., a thirty-two-year-old para VIII, entered the hospital January 9, 1934, in labor at term.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

x space in your columns for comment as in certain im-
portant respects the Report does not cover the ground as-
signed to it. The many aspects of the problem may tempt
me to go beyond the limits of a letter, but I shall try to
indicate what I have in mind to say.

The chief but not the only cause of the conditions
which are properly adversely criticized in the Report is
the lack of funds. This explains the Board's neglect in
showing up physicians who have failed to show cer-
tificates of registration to the town clerk. I might give
number of other instances of the difficulties of the Board,
but I shall restrict myself to general considerations.

It has been pointed out to the Board that its income is
derived from fees for examination and registration of ap-
plicant physicians, and that if, after registration, physi-
cians wish any service from the Board, they cannot ex-
pect it unless they pay for it. It may seem to be a new
point of view open to question as to propriety at least,
but this reason has been given as the explanation why
the Board has encountered so much difficulty in getting
appropriations to carry out what it thinks it should do.

It is pertinent at this point to quote from the statute on
requests for increased appropriations in the budget es-
timate. Section 3, Chapter 29 (*General Laws of Massa-
chusetts Tercentenary edition 1932*) reads in part as fol-
lows: "Every officer shall submit to the budget

commissioner estimates of the amounts required
for ordinary maintenance for the ensuing fiscal year,
with an explanation of any increased appropriations re-
commended and with citations of the statutes relating
therein. The said estimates shall not include any es-
timate for any new or special purposes or objects not
authorized by statute." It is easy to think of things
which would improve the usefulness of the office of the
town clerk, such, for example, as a geographical index, a list
of the physicians with their latest addresses, possibly
parade lists of removals, transfers, registrations in other
states, and deaths, but if any project involves the expendi-
ture of money and is not authorized by the statute, it
has no place in the budget.

It appears to me that the Committee is under a grave
misapprehension as to the meaning of "unregistered per-
sons practicing medicine," and in this connection it makes
a statement which is misleading. The Report says
that only does a physician have to register with the
town clerk, but he also has to register with the city or town
clerk. The statute has a different view. It says that
under certain conditions the applicant "shall be regis-
tered" by the Board, and the statute forbids the practice
of medicine by unregistered persons. It says further that
the town clerk "shall record the name of the owner of
each certificate" of registration upon blanks approved by
the Board, and it forbids the practice of medicine until
a certificate has been shown to the town clerk for such
recording. Nowhere in the statute is any person or body
authorized to register any person as a qualified physician
except the Board of Registration in Medicine, and most
of the Report is irrelevant to the purpose for which the
Committee was appointed, because it concerns itself with
physicians who have completed all the requirements for
registration and are truly registered but who failed to have
their names recorded with the town clerk. Their practice
may be illegal but it is not by "unregistered persons."

Perhaps I ought to stop here as there is so little of the
Report left, but it does contain some matter pertinent to
the discussion of matters other than the formal subject
of the study. In the fifth paragraph of the Report, the
Committee says that "it is considering only why so many
unregistered persons are said to be practicing medicine."
If this is all the Committee is considering, — and this is

well within its scope — why put so much else into the
Report? In the fourth paragraph the Committee express-
es itself as having been "compelled to ask why
they [the Board] think that one thousand" unregistered
persons are practicing medicine. If they felt compelled to
ask this question why did they not ask it of the Board
to whom alone, apparently, this thought is attributed? If
they really asked the Board this question are they deal-
ing fairly with the Board and with the Society in suppress-
ing the reply of the Board? The question is purely rhetori-
cal and has not been asked of the Board. The end of the
fourth paragraph is not clear. By implication the Com-
mittee has denied that the condition is as the Board al-
leges, and it then attempts to explain the cause of this
alleged condition the existence of which it has denied.
If the Committee had acknowledged that there is some
truth in the claim of the Board and had tried to explain
the situation as it is and not as it is alleged to be, the
argument might have been more impressive.

In the same paragraph occurs the following sentence
"Such conditions if true, not only reflect seriously on the
whole medical situation, but also on the Board it-
self." It is a fact that the whole medical situation, on
which reflection may properly be made, is more serious
than is generally recognized even by physicians. What,
indeed is the significance of the well-known fact that
what may be called perhaps, the most important piece
of medical legislation since the creation of the Board in
1894 namely the creation of the Approving Authority re-
sulted from a bill which was introduced not only without
the support of the Society but in direct opposition to the
advice of its officers?

Three other sentences in the fourth paragraph need
comment. The first reads "the Board which has
had the responsibility for forty-five years of protecting the
public against unregistered persons practicing medicine

"In justice to the Board, the extent of the responsi-
bility should be stated clearly and a recent case shows
how limited the responsibility actually is. It is important
to remember that responsibility is limited by the power
to do something. To what action is the Board then
limited? It was reported to the Board that a certain per-
son was practicing medicine without a license. In ac-
cordance with the statute, this was further reported by
the Board to the proper prosecuting authorities, the police,
and the responsibility of the Board stopped there, under
the statute. The matter was investigated there was Grand
Jury indictment, and the case was disposed of favorably to
the defendant without giving a single witness or the in-
vestigating the opportunity to appear in court. For the
Committee to say that the Board has the responsibility
(italics mine) is to speak without knowledge.

The Report says that the Committee asks why the
Board thinks men are practicing on dead men's certi-
ficates. I have never heard from the Board that it thinks
so. The Board has claimed that this may be so, and that
it was so in one instance in the past was shown by find-
ing after a physician had died that he had been practic-
ing on the license of another physician long since
dead. There may be other cases and it has been reported
to be the experience of other states, when the annual
registration law went into effect, to find several instances
of this unauthorized practice.

The reason why the Board thinks there are probably
a thousand persons, not registered by the Board, who are
practicing in Massachusetts, is that a comparison was
made with the state of New York where there was an
estimate from the experience in comparing carefully certain
selected areas as samples, and a count of persons who ac-

ually left the state when annual registration became effective. The resulting figure for Massachusetts on the basis of the relative number of physicians in the two states was about 1300. The Board has said 1000, a conservative estimate. All such figures are merely estimates, but support for the figure "1000" is given by the estimated number of chiropractors practicing chiefly under license to give massage, of physiotherapists who practice not under the direction of a physician, of persons practicing by the use of electrolysis (38 persons or organizations are listed in a recent telephone directory), of skin "specialists," of arch support prescribers, and the large number of "little" persons who peddle or prescribe their own little remedies. Perhaps this last group is the largest of all. Another sidelight on this question is thrown by the statute, in its list of groups of unregistered persons practicing medicine who are exempt from the penalty for violating the medical practice act. The very fact that they are listed as exempt means that in the eyes of the statute they are practicing medicine. I think it is a conservative estimate to place the figure at 1000 unregistered practitioners of medicine in Massachusetts. As most of the complaints about the practice of medicine by unregistered persons seem to be reported to the police before they come to the attention of the Board, I have directed inquiry to this quarter and the reply is that 1000 is a *very* conservative estimate.

Before I conclude I must say one word about the quotation from what the secretary of the Board is reported to have said in 1937. I do not recall the exact words I used on that occasion, — and when one speaks extemporaneously words have a strange way of slipping, — but I do not see how I could have said what was attributed to me, because I know I have never held all the views there expressed as mine. It is a fact, and contrary to the statement in the quotation, that the prime duty of the Board is to protect the public against physicians, against unqualified persons by refusing to admit to practice such as the Board finds unqualified, and by removing from practice persons whom it has licensed and who in its opinion have shown serious disqualification in practice.

In closing, I may say that my chief criticism of the Report of the Committee is that it has missed the mark. It might have limited itself to "unregistered persons practicing medicine," the formal restriction of its scope. But as to what registration means, it does not see eye to eye with the statute, the authority of which in this connection exceeds that of the dictionary. Or it might have transcended the mere title, if it had had the vision to see that control of unregistered persons is by necessary implication only a part of the whole problem of the regulation of the practice of medicine, and have discussed what it thought pertinent from this higher point of view. How defective the law and the procedure are, I suppose the Board of Registration in Medicine knows better than anyone else.

Now a really mature medical practice act, which is what the Committee might well have discussed if it once saw fit to go outside the narrow scope of its title, should contain three general provisions, with many details of course. There should be first a definition of what is to be regulated, that is, a definition of the practice of medicine. Without this the law cannot be well enforced. If no one knows what the practice of medicine is, it cannot be defined. If everybody knows, the definition should not be beyond the power of man to put in words. There should be next a statement as to who may practice, and all the qualifications therefor, and how they should be determined, and the regulations under which practice should be carried on, with penalties for violations, that is, penalties against unpermitted practice. There should be last a

procedure for stopping the practice of persons once found qualified, but later deemed to be unqualified.

For the last procedure, the statute has, since 1894, made fairly adequate provision. The second is still inadequate, although it is hoped that the Approving Authority may be a means of approaching a reasonable degree of adequacy. Annual registration is a mere detail. Massachusetts has always neglected the first provision and it remains almost the only state that fails in this respect.

No one who has not been closely connected with the work of the Board has any idea of the amount of work that is involved or of the difficulties under which it is carried on, yet its importance in protecting the health of the public is out of all proportion to the size of the budget. It is to be hoped that this conscientious and stimulating Report of the Committee will not merely direct the attention of the Society to the work of the Board, but will result in improving the conditions under which the Board is trying to protect the public against the improper practice of medicine.

STEPHEN RUSHMORE, M.D., *Secretary*,
Board of Registration in Medicine.

RESTORATION OF LICENSE

To the Editor This is to inform you that in accordance with the vote of the Board of Registration in Medicine, the license of Dr. William M. Walsh, 32 Edison Green, Dorchester, revoked on April 1, 1937, was restored on February 29, 1940.

STEPHEN RUSHMORE, M.D., *Secretary*

State House,
Boston

NOTICES

BOSTON DOCTORS' SYMPHONY ORCHESTRA

The Boston Doctors' Symphony Orchestra will rehearse under Alexander Theide, former concert master with the Cleveland Symphony Orchestra and the Philadelphia Symphony Orchestra, every Thursday at 8 30 p.m., in Studio A, Station WMEX, 70 Brookline Avenue, Boston. Those interested in becoming members should communicate with Dr. Julius Laman, Pelham Hall Hotel, Brookline (BEA 2430).

BOSTON MEDICAL HISTORY CLUB

There will be a meeting of the Boston Medical History Club at the Boston Medical Library, 8 Fenway, Boston, on Monday evening, March 18, at 8 15. Dr. Hyman Morrison will give an illustrated talk on "Early Chapters in a Life of Reginald Heber Fitz."

All interested persons are cordially invited to attend.

BOSTON HEALTH LEAGUE

The annual meeting of the Boston Health League will be held at The Sheraton, 91 Bay State Road, Boston, on Tuesday, March 19, at 12 30 o'clock. Dr. Clifton T. Perkins, Commissioner of Mental Health, will speak, his sub-

yet being "Present Activities of the Massachusetts Department of Mental Health."

Reservations for luncheon, \$1 a plate, should be made at the office of the Boston Health League, 80 Federal Street, before March 16 (LIB 8515)

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday March 20 from 2 to 4 p.m. Drs. Elliott C. Cutler and Soma Weiss will speak on "Anemia."

Physicians and students are cordially invited to attend.

CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in Carney Hospital Auditorium on Monday morning, March 25, at 11.30

PROGRAM

Recent Advances in Stomach Surgery Dr. Joseph Stanton.

Unstabilized Lumbosacral Joints End results of 250 lumbosacral fusions. Dr. Thomas F. Broderick.

Boce Tumors. Dr. Michael E. McGarty

Physicians and medical students are cordially invited to attend.

GEORGE W. GAY LECTURE

The George W. Gay Lecture on Medical Ethics will be given on Tuesday March 19 at 5:00 p.m. in Amphitheater E of the Harvard Medical School. Mr. Phillips Ketchum, of Boston will speak on the subject "How Does a Doctor Spend His Money?"

TUFTS COLLEGE MEDICAL SCHOOL ALUMNI ASSOCIATION

The annual meeting and dinner of the Tufts College Medical School Alumni Association will be held Wednesday evening March 27 at the Hotel Somerset, Boston at 7.00. A short business meeting at 6.30 will precede the dinner.

Dr. Timothy J. Leary will introduce Professor Alan R. Montz, who will speak on "Tales that Dead Men Tell." The cost of the dinner including dues will be \$3.50

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The New England Society of Physical Medicine will meet at the New England Sanatorium and Hospital Melrose, on Wednesday evening, March 20. Following a dinner at 6.30 the program will be presented in the gymnasium, at 7.15

PROGRAM

Principles of Hydrotherapy Dr. C. A. Haysmer
Practical Application of Hydrotherapy Including Hubbard Tank, Whirlpool Bath and Nauheim Bath in New Unit. Dr. W. A. Ruble.

All members of the medical profession are cordially invited to attend the meeting.

NEW ENGLAND PATHOLOGICAL SOCIETY

The next meeting of the New England Pathological Society will be held on Friday March 29 at 8:00 p.m. at the Peter Bent Brigham Hospital.

PROGRAM

Forensic Pathology Dr. Alan R. Montz.
Business meeting.

Physicians and students are cordially invited to attend

AMERICAN HEART ASSOCIATION

The Sixteenth Scientific Sessions of the American Heart Association will be held at the Hotel Roosevelt New York City on Friday and Saturday June 7 and 8

The general cardiac program will be given on Friday and the program of the section for the study of the peripheral circulation on Saturday

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY MARCH 17

SUNDAY MARCH 17

4 p.m. Doctor Will My Baby Be Normal? Dr. Charles P. Sheldon. Illustrated, public, health lecture. Faulkner Hospital Auditorium.

MONDAY MARCH 18

8.15 p.m. Early Chapters in a Life of Reginald Heber Fitz. Dr. Hyman Morrison. Boston Medical History Club. Boston Medical Library 8 Ferry

TUESDAY MARCH 19

9-10 a.m. Clinicopathological conference. Dr. D. S. King. Joseph H. Pratt Diagnostic Hospital.

12 m. The Clinical Significance of the Collateral Circulation in Patients with Angina Pectoris. Dr. Herman Blomgart. South End Medical Club. Headquarters of the Boston Tuberculosis Association 554 Columbus Avenue, Boston

12.30 p.m. Present Activities of the Massachusetts Department of Mental Health. Dr. Clifford T. Perkins. Boston Health League. The Sheraton, 91 Bay State Road, Boston

5 p.m. How Does a Doctor Spend His Money? Mr. Phillips Ketchum. George W. Gay Lecture on Medical Ethics. Harvard Medical School Amphitheater E.

WEDNESDAY MARCH 20

9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

2-4 p.m. Anemia. Drs. Elliott C. Cutler and Soma Weiss. Peter Bent Brigham Hospital

THURSDAY MARCH 21

9-10 a.m. Control of Gonococcal Infection. Dr. O. F. Cox. Joseph H. Pratt Diagnostic Hospital

FRIDAY MARCH 22

9-10 a.m. Psychotherapy. Dr. Donald MacPheron. Joseph H. Pratt Diagnostic Hospital

SATURDAY MARCH 23

9-10 a.m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital

BOOK REVIEWS

Cancer of the Larynx Chevalier Jackson and Chevalier L. Jackson 309 pp. Philadelphia and London W. B. Saunders Co., 1939 \$8.00

With the constant expansion of medical knowledge, such specialized subjects as cancer of the larynx now pass from simple inclusion in textbooks to the importance of the monograph. When the authors bring to their book the wide knowledge and clinical experience of the Jacksons, father and son, one may expect a most comprehensive consideration of the subject.

The arrangement of this book is most satisfactory in its clear-cut segregation of the many aspects involved in a discussion of cancer of the larynx. The early chapters deal only with the technical procedures incident to the diagnosis of the lesion by mirror examination and biopsy by direct laryngoscopy. Then follow descriptions of the procedures of laryngofissure and laryngectomy, exhaustively described and freely illustrated with both line drawings and colored plates by the authors. No effort is spared to

make clear the minute steps in operative technique. Full consideration is given to the therapeutic use of x-rays and radium, as well as to palliative measures in inoperable conditions. In a second major division, attention is directed to exceptional cases, rare types of laryngeal growth, borderline and precancerous conditions, etiology, prophylaxis, general considerations and controversial phases of the subject. Free use has been made of photomicrographs and of colored illustrations of the actual picture seen at mirror laryngoscopy. The segregation of the first part of the book into two parts clearly avoids the confusion which might result from an attempt to discuss operative technique and clinical considerations in combination.

The final third of the book presents a historical and chronological picture of the development of laryngeal surgery, with brief accounts of the work of the many pioneers who have contributed to the present status of our knowledge of laryngeal cancer. An extensive bibliography makes available almost all the literature pertinent to the subject.

As a whole there is presented an exhaustive account of the pathology of laryngeal cancer, the methods available for its diagnosis and, in satisfying detail, the operative and non-operative maneuvers now appropriate for its eradication and cure.

The Neurogenic Bladder Frederick C. McLellan. 206 pp. Springfield, Illinois, and Baltimore Charles C. Thomas, 1939 \$4.00

This book purports to be a study of the alterations in function of the urinary bladder resulting from various forms of disease or lesions of the spinal cord and brain, as determined by the cystometrogram.

It is very loosely written and therefore very disappointing, coming as it does from one of the outstanding teaching clinics. For instance, in each of the first three illustrations, which are copied from the literature, either the name of the authority is misspelled or the title of the communication misquoted. Even worse than this is the writer's diction, which in many places is so clouded as to leave the reader in complete darkness as to its meaning. The third sentence of the book reads "This organ has a sensory distribution which parallels roughly that of the skin." He means "the bladder," though this has not yet been mentioned, and that it is supplied by "sensory nerves." Or again (page 64) "Progressive advance of supranuclear lesions involving the nuclear [sic] of infranuclear areas will produce this bladder." Certainly a new way of producing a bladder! Still further (page 101) "In view of the high incidence of both spina bifida occulta and enuresis, there certainly would be no great odds for coincidence in this situation."

In short then, in its present form this publication entirely fails to carry conviction. Some forty-nine charts are published supposed to illustrate the various sorts of deviations from the normal shown by the cystometer. One cannot avoid the thought, in view of what has preceded them, that these two have been so inaccurately assembled as to be of little value.

Medical Record Visiting List or Physicians' Diary for 1940 Revised. Baltimore William Wood & Co., 1939 \$2.00.

This pocket size visiting list is made in three sizes, for thirty, sixty or ninety patients a week. The record is preceded by twenty-seven pages of dosage tables, poison antidotes and like material.

MEDICAL EDUCATION

A. LAWRENCE LOWELL

BOSTON

HAVING been asked to write out for the *New England Journal of Medicine* some informal remarks which I made last June at the Harvard Medical School to the Class of 1914 on the twenty-fifth anniversary of its graduation, I send these pages. The excuse for the remarks was that 'old men plant trees,' which means that as they can not expect to see the fruition of plans they propose, or ideas they suggest, they are free to dream about them. In this spirit I made the observations to the class, the substance of which I repeat here as well as I can.

Education in medicine is more difficult than that in any other profession, because it involves the knowledge of many subjects which, apart from their relation to medicine, have no natural connection. In a school of law or engineering, for example, the various topics studied are either different phases of the same general subject, or, like mathematics in engineering, a tool for the solution of its problems. In a medical curriculum, on the contrary, gross anatomy has to the beginner no obvious connection as a tool or otherwise with biological chemistry, bacteriology or pharmacology. Each involves a brute effort of memory without much help from educational mnemonics, and is largely forgotten before the time comes for its application to the practice of medicine or surgery. The student learns anatomy and forgets much of it, physiology and forgets much of it, and so on throughout his course.

I recall the remark of a professor in a special field, that he always described in a lecture to his class a very rare disease of which he felt that his students ought to have heard, although he knew they would remember nothing about it. Perhaps the result was merely confusion in the less perceptive members of the class, rather than a clearer conception of the general aspects of medicine. Whether there is an advantage in learning more facts than can be retained depends upon

the nature of those facts and their effect upon the mind. When fresh illustrations of a thought or action tend to produce familiarity with the idea or process, and thus render it more easily and better reproduced it is well. This is true of making a diagnosis or watching an operation, but it is not true of striving to memorize more discrete facts than the ordinary human mind can retain and utilize, and every physician knows that medical knowledge has far passed that point today. Therefore it should be more and more recognized as having done so, and selection of basic topics ought frankly to replace the attempt at omniscience. No doubt this has been done to a large extent, but the outside observer feels that it ought to be done with greater system.

No other professional education attempts to cover so large a part of its possible field of knowledge for its students, nor could it do so without obliging them to spend the better part of their lives in learning many specific things that they will never use. In former times the physician was expected to make a diagnosis on his first visit to the bedside, on peril of being thought ignorant if he failed to do so, but that has long passed, and in any complex case he takes blood and cultures, reserving his final opinion until these have been examined in the laboratory.

There is, in fact, a very real disadvantage in the present length of medical education, and that is the late age at which physicians and surgeons are able to begin active practice. The course at most first-class medical schools is now four years, followed by an average of about two years in a hospital, and longer with those most ambitious to perfect themselves. If a man goes through a college, he spends nearly two years of it in pre-medical studies, entering college at an average age of eighteen years and three months, thus graduating at twenty-two years and three months. That means that he gets through the medical school and

hospital not earlier than twenty-six—far older than a man ought to be when he begins his work in life, and in most cases too near the end of the age of greatest intellectual fertility

At the other end of his career, if he has an appointment of service in a hospital he loses it, as a rule, at sixty-two, and very commonly his private practice therewith. Some years ago one of our clinical professors retired from the hospital at the regular age, and also from the medical school because he had lost his clinic. His former students and colleagues gave him a dinner which received much publicity, and produced the impression that he was bidding farewell to medicine whereat he lost the private practice he had hoped to continue. A little later a colleague, on retiring, was offered a complimentary banquet, but prudently declined it. Perhaps the age of retirement is too early or too late—too early if it means withdrawing from the community the benefit of his experience, too late if it means turning over to his juniors the bulk of the work at the hospital, while retaining some supervision and a sufficient teaching clinic.

As things stand, the man with a permanent hospital appointment—out of a useful life which could last, let us say, on the average until seventy—has a maximum of some thirty-six years for acquiring and conducting a practice, to which he has devoted, including the two premedical years, a minimum of eight to professional training. That seems disproportionate, and, what is more, the length of training has been increasing, and the age of hospital retirement becoming lower, until the outside scoffer wonders how soon the time to leave will arrive before the preparation for appointment is complete.

It is curious to compare the position of the clinical with that of the laboratory teacher. The latter may be appointed to a position of some sort in the medical school at any period after graduation therefrom, if he shows ability, and may hold his place as late in life as the general policy of the university permits. More depends upon the progress and the value of the man, less upon dates and periods.

Now let us look at these facts, beginning with the college. In the last half-century the age of entering Harvard, and no doubt other colleges, has been reduced almost exactly one year from nineteen and three months to eighteen and three months. Personally, I should like to see it fall six months more, for I think reasonably intelligent young men are perfectly capable of excellent intellectual development at that period of life. I

should much regret to have the students of our best medical schools lose the benefit of contact with other young men in a college of liberal arts the more so because I now lament the withdrawal, as compared with former times, of the medical profession from civic affairs to which they could contribute so much.

In regard to the next stage, that of the medical school, one who has had a chance to see it only from the faculty table must speak with great diffidence, and yet he may get some impressions not wholly without value because detached from the interest of teachers in their specific fields. That interest was in earlier days truly formidable. One sees it in the planning of the present Harvard Medical School, with its four separate and distinct establishments for the four chief laboratory subjects, each capable of containing an entire class, with its big lecture room unused three-quarters of the time. The impression is that those who planned the school intended to exclude from anatomy and from physiology, for example, any infiltration of the other as something alien to its nature. The old conception was the attainment of medical knowledge by study of many distinct and separate fields, that of the present, is correlating those fields into one great subject of medicine as a coherent whole, and to do this by an even more rapid process seems not impossible.

One sees the old conception again in the former attitude of the laboratory and clinical professors toward each other. They sat on opposite sides of the faculty table, and if an additional appointment were made to one group it was expected by the other also, that the balance might be maintained. It was like the days before the Civil War, when if a free state was admitted to the Union a slave state must come in to match it. Such an attitude in the medical school is inconceivable to-day. The clinic makes constant use of a laboratory, and the laboratory teacher appreciates more fully that his ultimate aim is fitting men for practice.

The interest of the medical teacher in his specific field as something distinct and separable from medicine as a whole has been greatly reduced partly by a better recognition of the interrelation of all scientific knowledge which has broken down artificial distinctions, partly in the Harvard Medical School by the general examination for graduation which has caused both student and teacher to correlate laboratory and clinical knowledge in a striking way. It is strange that this highly effective device has been little copied in other medical schools, for people still regard examinations mainly as a test of work done, whereas their most

important function is setting a standard of accomplishment.

Notwithstanding the advances made, there does seem to be still some needless attempt to cover too much ground, and it is possible that by a better correlation of structure and function, of laboratory and clinic, some forgetfulness could be saved, and to forget means waste of time in medical education. Failure to remember much that has been learned is inevitable, but oblivion due to needless lack of foresight in the sequence of the subjects taught is clearly to be avoided in a school of medicine. It means the loss of time, and time—that is, the length of the period required for professional training—is a vital matter in medical education today.

For a non professional observer to attempt to tell experts how to improve their methods would be presumptuous and provoke derision, but he may properly observe that the results are in some re-

spects defective from the standpoint of the community and of the profession. He may point out defects and suggest that they take them into consideration.

Vast improvements in medical education have been made in the last half-century, but in making them there seems to have been a tendency to add the new to the old without sufficient effort to eliminate some things no longer needed, to consolidate and simplify the curriculum—including the hospital part thereof—to make it more consistent, easier to grasp as a whole. All honor, nevertheless, to the men who have brought it to the present state. In view of the enormous increase in medical knowledge they have done wonders, but they would be the last to claim, or to hold, that they had reached perfection or, in the words of our own Oliver Wendell Holmes, that the time has come to expect that Heaven declare its final dividend.

ALTERNATING TREMOR (PARALYSIS AGITANS) AND ATHETOSIS*

Recent Advances in Diagnosis and Treatment

TRACY J. PUTNAM, M.D.†

NEW YORK CITY

THERE is a natural tendency to suppose that obscure conditions the symptoms of which display some similarities are due to similar disease processes. Doubtless for this reason, it has been the custom to group together Parkinson's disease, postencephalitic tremor, Sydenham's chorea, cerebellar tremor, Huntington's chorea, athetosis, dystonia and other entities. Formerly even the tremor of Graves' disease was often included. From this group I shall attempt to pick out and reassemble two categories, which appear to be well defined physiologically, and which are ordinarily due to a limited number of disease processes. These two may be denominated as alternating tremor and athetosis.

ALTERNATING TREMOR

The most familiar example of alternating tremor or is paralysis agitans of the elderly, which, as we all know, was described by James Parkinson¹ in 1817. His clinical description, easily available in reprinted form, has scarcely been equaled since. He noticed the persistence of tremor in certain

groups of muscles, its rhythmic, alternating quality, the fact that it may disappear during voluntary activity (or rarely be exaggerated) and the rigidity and weakness which accompany it. The pathological basis of the disease is now recognized to be an arteriosclerotic atrophy of the globus pallidus and substantia nigra.² This is often associated with scattered lesions throughout the nervous system, which are doubtless responsible for the mild defects of the pyramidal system and consequent paresis of voluntary motion often found, and also for general cortical atrophy and intellectual enfeeblement, either of which may or may not coexist.

Since the pandemic of encephalitis of 1918-1925, juvenile forms of the same physiologic disturbance have become almost commoner than the senile form. At first, a history of encephalitis was usually obtainable from the former group of patients, but in the presenile cases in which the onset has taken place in recent years, such a history is the exception rather than the rule. There seems to be a tendency for the senile and presenile groups to merge, so that now the commonest decade for onset is the fifth.³

A similar syndrome is rarely seen following head

*Read at the annual meeting of the New Hampshire Medical Society, Manchester, June 7, 1939. From the Neurological Unit, Boston City Hospital, and the Department of Neurology, Harvard Medical School.
†Formerly head of Neurological Department, Boston City Hospital; professor of neurology and neurosurgery, Columbia University College of Physicians and Surgeons; director of Services of Neurology and Neurosurgery, Neurological Institute, New York City.

injuries in young people, more rarely still as a result of multiple sclerosis, chorea and a scatter of other etiologic entities

Clinical Manifestations

The diagnosis is unmistakable in typical cases, which all physicians have seen. A few signs are to be watched for in doubtful cases. To be included in this category the tremor must affect chiefly the distal portion of the affected extremities, and have a regular rate of 5 to 8 per second, varying scarcely at all from day to day or from limb to limb.

Early signs are a loss of the normal swinging of the arms in walking, immobility of the face and eyes, failure to move the feet under the center of gravity in rising from a chair and inability to cross the legs in sitting. If the patient is asked to wink rapidly, the eyelids tend to lag after one or two closures. If the forehead is tapped with a hammer, the eyelids tend to go into spasm. As the patient attempts to touch his forefinger with his thumb repeatedly and rapidly, the two digits seem to "freeze" together. In contrast to this disability, the patient easily catches a ball or a roll of paper which is thrown to him, tosses it back and again becomes immobile.⁴

Special Physiological Studies

With special recording devices, the best of which is the electromyograph, the following additional points may be made out: as the flexors contract, the extensors relax completely, and vice versa. The bursts of contraction appear simultaneously in many of the motor units (groups of muscle fibers innervated by a single anterior horn cell). This is unlike normal voluntary movement, which is sustained by a series of overlapping asynchronous discharges of motor units. Rigidity when present is produced by a simultaneous innervation of protagonist and antagonist muscles.⁵

Medical Treatment

None of the ordinary disease processes underlying the syndrome just described are susceptible of successful treatment. At present, our only resource is to attack the physiologic disturbance rather than its cause. The same types of remedy are therefore applicable to all the clinical varieties of alternating tremor, but the amount of success that they promise is inversely proportional to the extent of the lesions and to the patient's age.

The standard treatment of paralysis agitans of all types is the use of drugs of the hyoscin series (Charcot,⁶ 1867). They should always be tried, though the results are often disappointing. Convenient forms are the 2½-gr pills of stramonium

leaves or the ordinary 1/100-gr hyoscin tablets. Either may be used three times a day, and rather rapidly pushed until the patient develops toxic symptoms. Recently a "wine of Bulgarian bella donna" (not yet on the market) has been given extensive trial, it is of questionable advantage over older forms, but may be tried if they fail. The dose is 5 drops after each meal, increased by 5 drops a day to the point of tolerance.⁷ The capacity of patients with paralysis agitans for drugs of this series is sometimes enormous, one of my patients took 1/3 gr of hyoscin daily over several days. The unpleasant symptoms may often be mitigated by giving pilocarpine, 1/8 gr three times a day by mouth.

The effect of drugs of the atropine series is sometimes increased by the use of amphetamine (Benzedrine sulfate) by mouth, in doses of 10 mg or more. This is particularly effective against the tics, such as oculogyric crises, that often complicate the postencephalitic type of the syndrome. Patients also tend to feel stronger and more alert when taking amphetamine. It is seldom effective in the senile group.⁸

Other drugs are on trial. Certain modifications of atropin and synthetics have been recommended.⁹ In the experience of our clinic, they are seldom more effective than the official drugs. Curare has been injected with promising results, but is too cumbersome and dangerous for routine use at present. Alcohol in the form of ordinary liquors is a great relief to some patients, and the barbiturates (except phenobarbital¹⁰) are worth trying.

Exercises and psychotherapy have been recommended, but are seldom of decisive value.

Surgical Treatment

In some cases of alternating tremor, of whatever origin, the situation is sufficiently distressing to warrant surgical intervention. Success has been reported from operations of two general types: resection of the motor¹¹ or premotor¹² cortex, and section of the pyramidal tract.¹³ As regards the tremor, the result is often striking: it is abolished or reduced to an insignificant remnant. The more extensive cortical operations produce a severe monoplegia, however. It is still uncertain whether favorable results can be obtained by removal of more restricted areas, with less disability. Section of the lateral pyramidal tract in the cord is followed by less disturbance in the use of the hand, but the leg is also rendered somewhat spastic—a desirable alternative to tremor, but a loss if it was formerly unaffected. Whether any of these operations can be used in bilateral cases is open to question, and of course the patient's age and general condition must be carefully considered. The

whole subject is a new one, and the indications for operation will doubtless grow clearer in the next few years.

My own operative experience includes 3 cases in which a complete section of the lateral pyramidal tract was performed on one side, 3 in which a partial section was done and 1 in which a cortical operation was carried out. There were no operative deaths. All patients were improved, moderately or greatly.

ATHETOSIS

Under this term may be included at least many examples of the syndromes of spasmodic torticollis, dystonia musculorum deformans, hemiballism and posthemiplegic chorea. The etiology of most of these conditions is obscure. In many cases there is a history of birth injury or asphyxia. Occasionally they are familial. It is somewhat unusual to be able to trace the disturbance to a vascular accident or injury.

Irrespective of its origin, the disease process affects the basal nuclei, predominantly the caudate. The changes, which may be slight, are usually demonstrable by encephalography.

Physiology

Irrespective of etiology, the diseases included under the term "athetosis" have in common a persistent, irregular involuntary spasm of the muscles involved. Protagonists and antagonists are simultaneously affected, so that the excursions are usually slow, and attended with a considerable output of energy. As a result, the patient perspires, his metabolism rises and the muscles hypertrophy (which seldom occurs in paralysis agitans). While there is seldom a definite pattern or rhythm to the involuntary motions, they are often restricted to one part of the body—the face, tongue, neck, one or both arms, one side or the entire body. The leg is rarely affected alone. The grotesque postures and gestures which the unfortunate victims make often cause them to be regarded quite unjustly as feeble-minded. The movements are more severe when the patient attempts voluntary movement, and also when he is embarrassed or knows that he is being observed—a circumstance which has led to the erroneous opinion that the whole syndrome is of psychogenic origin.

Athetosis of one or more extremities—or even of the entire body—may be accompanied by complete or almost complete voluntary paralysis. In this event, signs of pyramidal tract defect are demonstrable. An alternating tremor may also co-exist.¹⁴

Electromyography shows that the motor units discharge in a normal polyrhythmic fashion, which

doubtless accounts for the rather remarkable rarity of fatigue. What is abnormal is the fact that there is no relaxation of antagonists, and that the movements are involuntary.¹⁵

Medical Treatment

The method of treatment most commonly used is re-education of the affected muscles. The patient is encouraged to take corrective exercises, and practices certain skills under supervision. He is urged to appreciate the sensation of relaxation of muscles and voluntary innervation of movements.¹⁶

This method has been reported^{16, 17} to yield excellent results in certain cases, although from the published accounts it is often difficult to be sure how much of the improvement was in the associated hemiplegic disturbances. In the cases I have seen and followed, the method has produced relatively little in the way of favorable results. There is, of course, no harm in trying it, but in every case the progress should be carefully followed by means of motion-picture records.

Treatment by drugs has in the past been wholly unsuccessful. There seems to be some hope that the use of curare or drugs of similar action may be beneficial,¹⁸ but many difficulties and dangers must be overcome before they can find wide acceptance.

Surgical Treatment

Innumerable orthopedic operations (tendon lengthenings, transplantations, nerve sections) have been employed in the treatment of athetosis, usually without success. Posterior root section is of no value.

The first successful surgical treatment was that applied by Horsley¹⁹ in 1909. He resected the corresponding motor cortex, with relief of the abnormal movements, but a cortical monoplegia resulted. This operation has been used intermittently, and has recently been revived by Bucy and his collaborators,^{20, 21} Sachs²² and Klemme.¹² The reported results are good, but Bucy who has given the matter particular study, recommends it only for cases in which one arm alone is chiefly involved, and the extremity is already useless.

The operation of section of extrapyramidal tracts in the anterior column of the spinal cord, for athetosis, was introduced at the Neurological Unit in 1931.²³ To date, 50 operations have been performed, in 38 cases. There have been 4 operative deaths, of which only 1 (from pneumonia, two weeks after operation) occurred in the last 25 cases. The proportion of improvement is difficult to estimate, 5 patients have been enabled to seek employment and most of the remainder are well.

pleased with the result of the operation, even when the advance consists in no more than being able to lie quietly in bed or sit up in a chair, if this has previously been impossible. In no case has there been complete relief, but the improvement which is secured by the end of convalescence is permanent, unless the progress of the disease destroys other parts of the brain.^{14 23}

Favorable results with this type of operation have also been reported by Oldberg²⁴ and by Machansky.²⁵

SUMMARY

A review of the various subvarieties of alternating tremor (paralysis agitans) and of athetosis (torticollis, dystonia, hemiballism) is presented, including a brief physiological analysis of their manifestations. The methods of treatment of both diseases by drugs, new and old, by retraining and by the various types of operation recently introduced are described, and an attempt is made to evaluate the indications for each and the results to be expected.

THE QUALITY OF MEDICINE*

NATHAN B VAN ETEN, M.D.†

NEW YORK CITY

WHAT kind of medicine do you want? Do you want England's medicine, or Hitler's medicine, or Stalin's medicine, or New Zealand's medicine, or American medicine?

Do you want socialized medicine, or state medicine, or democratic medicine? Do you want impersonal medical care or do you want free choice? Do you want bureau medicine, or medicine fostered and promoted by those who have been especially dedicated to the service of the sick? Do you want the doctor an employee of the state working limited hours for a salary?

Are they we be dominated by dictators or by the of alter the people? The future of medicine will that they p by our citizens. If they are ignorant of the of medicine will suffer, if they are

The standard American medicine may go forward all types is the survived the rise and fall of many (Charcot,⁶ 1st

though the presented at the annual meeting of the Vermont State Medical Association October 5 1939 venient form American Medical Association

civilizations. I predict that its advances can be delayed only temporarily, and that they will attain greater heights long after the actors of the present generation have left the stage.

An inspired propagandist says that there are forty million people in the United States who are suffering from the lack of medical care because their incomes are less than eight hundred dollars, with the consequence that they are unable to maintain adequate standards of living. The remedy he prescribes is socialized medicine after the European manner. He views American evolution as immature because we hesitate to embrace social systems which seem to have failed in Europe, and to be poor substitutes for developing programs which have brought medical care in America to higher accomplishments than anywhere else.

The propagandist admits American superiority, which he credits to a higher standard of living. When he contrasts small countries, whose populations are homogeneous, to polyglot America, he

says us a real tribute. The difficulty of matching Denmark in the eradication of syphilis is obvious, but American medicine is enlisted in the fight for that objective.

He says with finality that there is no further need for surveys to uncover the lack of medical care of the unfortunate forty millions—that we now know all there is to know about these neglected people. On the contrary, I believe that there is more need than ever to discover the extent of human suffering among those who are existing miserably and the extent to which medical care fails to reach them.

Every city in the United States has thousands of people who are handicapped by bad housing. Senator Wagner is quoted as saying that there are over four hundred thousand people in the City of New York who live in buildings unfit for human habitation. I can very well believe that story when I am told that there are two hundred and fifty thousand bedrooms in New York City which have no windows. Many of these rooms have multiple occupancy, and all are potentially pestiferous. The government administered City of Washington is said to lead all our cities in slum miseries, as it also leads in the statistics of morbidity. Every one of these city dwellers must be included in the city mullion, but none of them can claim to be outside the areas of free hospital and medical care. Every citizen of the City of New York may have emergency medical care free of cost at any moment of the day or night if he asks for it. We can well believe that it is seldom asked for when the need is not acute through accidental or tragic illness.

Many small towns have hospital facilities available to people whose incomes are eight hundred dollars or less, or who have no income at all, and where a generous medical profession cares for them free or at charges within their means. Many farmers fail to see eight hundred dollars in any year, and still are able to pay for medical care.

No one can deny that there are communities which are poorly supplied with medical care as well as poorly fed and clothed and housed. No one can deny that eleven million people are unemployed. No one can deny that there are still in a few sections of this country where the birth rate is still out of proportion to the supply of food or education.

No one can deny that there are local needs for hospital beds—while at the same time 20 per cent of all hospital beds are unoccupied. It is, however, not a survey but a distortion that tries to show that forty million people are failing to receive medical care, while at the same time death rates are steadily falling. In New York City the sta-

tistics for 1939 are all showing new low records. This is an accomplishment of American medicine. Americans are so hospital-conscious that sixteen people enter a hospital every minute day and night. A baby is born every fourteen seconds, and half these births occur in hospitals.

The fact that 47 per cent of all our hospital beds are occupied by insane people cannot be charged entirely to the failures of medical care, while much of it must be credited to social maladjustments. Surveys are needed more than ever. The Medical Society of the State of New Jersey has just finished a survey which might well serve as a model to reveal the true conditions in every state. It did not make estimates from occasional samplings of the population, but reported every county and every township. This is not too difficult a task and must be done to discover all the facts of supply and distribution and need of medical care.

Every physician in the United States must be enlisted in the search for the truth on which to build the foundations for a master plan. The improvement of living conditions is preventive medicine. It is both a national and a local problem. The New York situation probably involves greater difficulty and cost than are encountered in other cities, but it can be cured by New York money and New York effort. It might be well if the national government would show the world how to do it by staging a demonstration in the District of Columbia. I believe that every physician in the land should get behind slum clearance and demand action from all local and national authorities.

The propagandist proposes to cure all our health deficiencies by imposing upon the American people some of the European systems of sickness insurance. Sickness insurance abroad has not reduced morbidity or mortality, or the loss of time of the worker due to sickness. Foreign sickness insurance does not take care of the indigent. The indigent person is outside the field of insurance and is the problem of the taxpayer.

We must remember our own troubles with compulsory workmen's compensation insurance. Although this procedure has been greatly improved, we must not forget the scandals which accompanied it and which still require constant vigilance.

Although the propagandist admits that health insurance is not a panacea, he thinks that while it is not the ideal system, under the present social and economic conditions of the country compulsory health insurance, combined with extension of public health services, is the best possible solution. The propagandist wobbles again when he advocates the Wagner Health Act and says that it neither carries nor advocates a health insurance scheme. This bill

was introduced on February 28, 1939, on March 29, just a month later, as was expected, the senator's son, Robert F. Wagner, Jr., a member of the Assembly of the State of New York, introduced a compulsory health-insurance bill in contemplation of enactment of the federal measure. Cash benefits for disability and maternity care, he said, were included, because the federal bill makes provisions for aid to the states that provide such assistance. The Wagner Health Act opens the door to potential graft of vast dimensions.

Very few people budget their incomes for anything except rent, heat and light. Budgeting for sickness is now being inspired by hospital and medical service plans which involve small daily payments. These plans, now subscribed to by more than three million people, are helpful to many people and indirectly to physicians, but the experience of the past year has demonstrated such serious abuses of privilege by greedy subscribers that financial collapse is threatening, unless contracts are definitely limited and rigidly enforced. Surpluses melt away under excessive hospitalization, and the purposes of group service are defeated.

It seems inevitable that the insurance principle will be involved in plans for medical service, and it seems wise that many trials be made in the various states, such as are now proceeding in California and New Jersey. The medical profession has developed the high quality of medical care that we now enjoy, and earnestly desires to make it still better.

The propagandist asks whether the quality of medical care is really good in rural districts, where, he says, many doctors still practice horse-and-buggy medicine. I should answer that query by saying that the country doctor has given a very good account of himself, and that the quality of care given to people of small or moderate means in rural districts is often of the highest type.

The general practitioner is the backbone of medicine. In my opinion he would be ruined if he were subsidized. He does the best he can for each of his patients because that is the only way he knows to hold his practice, and he has an honest desire to restore his patients to functional usefulness. By and large the general practitioner is God-fearing—keeps the Decalogue and cherishes his sworn obligations. I should like him to take a more serious interest in local political machinery, and to use his great influence in the betterment of the public health through the practice of preventive medicine. I should like him to realize how great is his potentiality in stimulating his patients and all their contacts in the guidance and in-

formation of legislators who seldom understand the physician's viewpoint.

Every physician should have a copy of the proposed Wagner Act and should be shown the danger to himself of its provisions. Every physician should in turn advise all his patients and acquaintances of this danger, at once, and should ask them to bring pressure to bear on their legislative representatives, state and national, to defeat this legislation.

Although this measure was not acted on at the last session of Congress, it will appear at the next in amended form with an emotional appeal for the spending of millions for the promotion of public welfare—just another act in an orgy of spending for prosperity, and of handing over the practice of medicine to bureaus in Washington. Everyone should know that the estimated overhead expense of these bureaus in the administration of this act will be six million dollars. Sending a dollar to Washington does not make it bigger. I am convinced that this state will be better off by keeping its money at home—by developing the strength of its own department of health and by supporting its physicians in the practice of better medicine for all the citizens.

You must not take a negative position. Through the influence of systematized adverse propaganda, an impression has been created that the medical profession, and especially the American Medical Association, is against all progress, against any change in delivering medical care, and is acting in restraint of those who would try new plans. People should be told that these statements are untrue and unfairly presented, and should be told what American medicine really stands for.

Over a hundred years ago, in 1835, the vital statistics of Philadelphia revealed that the average expectation of life was twenty-one years. Preventive medicine, carried on by doctors, mostly private practitioners, in the United States, has raised life expectancy to above sixty years. This has been accomplished largely through the salvage of children who otherwise would have died from the ravages of communicable diseases.

One hundred and fourteen thousand of the one hundred and twenty-five thousand actively practicing physicians of the United States are members of the American Medical Association. This is organized medicine. Organized medicine stands for the protection of children from all communicable diseases by scientific methods and for the care and improvement of deformed or crippled children, for the protection of children from accident and injury, from blindness, from the exhaustion of child labor and from tuberculosis. It stands for nutritional improvement. Organized medicine,

through private practitioners and hospital practitioners, has been steadily improving the growth and health of children for many years.

Organized medicine is intensely interested in race improvement and in the science of immunology. It gets very little help from legislators for the promotion of compulsory vaccination against smallpox. Thousands of children evade vaccination. Thousands of cases of smallpox, all preventable, prevail at all times in this worst vaccinated of all civilized countries. One case appeared in New York City last month and 14,335 were reported last year in the United States.

Organized medicine is constantly studying the problem of maternal mortality, and recent statistics show substantial gains in a nation-wide effort to salvage future mothers. It stands for prevention of communicable venereal diseases, for public health, for sanitation, for good education, for good food and drug laws, for good housing. It stands for better education of physicians, in order to implement them for the practice of better medicine.

It stands for having all the hospital beds that are needed, placed where they are needed. It is for all the state medicine that is needed for the care of the insane, the feeble-minded, the tuberculous and the indigent. It is for every effort that can be made by public-health services for the eradication of syphilis. It is for preventive medicine of all kinds. It is for co-ordination of all national health services, except those of the Army and Navy, into a national health department headed by a secretary of health.

It is against compulsory sickness insurance, and against the administration of medical practice by national bureaus. It is for the preservation of the practice of medicine by the family physician, so far as possible.

The old family doctor has nearly finished his career. He has carried the tradition of true philanthropy into every personal relation. His devotion to his self-imposed obligations has kept him out of the public notice. He quietly answers the call of the sick without self-consciousness or self-pity. He carries on unnoticed, unless like Doctor Dafoe he officiates at a quintuplet delivery or performs some dramatic service which is heralded in headlines. His skill is unknown beyond the immediate circle of his limited acquaintance. He never advertises. He holds no public office. He cannot leave his patients long enough to go to the legislature. His place is at home, trying to keep people well or curing the sick. His influence on public affairs is small because he is too busy to become an active partisan. He does not make much of an income because he is generously appreciative of the financial difficulties of his patients.

He is no longer a saddle bag doctor dispensing empiricisms. He no longer drives a characteristic gig. His high hat and his gold-headed cane are no longer symbolic. He has been well educated in the medicine of his period. His preceptorial training in the use of his powers of observation, in deduction and in the high development of his own senses, often more than five of them, has yielded to the deeper searching into the mysteries of bacteriology and of internal secretions. He has learned the value of mechanical helps. Unless he has been practicing longer than fifty years he is not an old doctor at all. Within fifty years he has become a modern doctor, because modern medicine is all measured within this last half-century. The metamorphosis of the old family doctor has been so gradual that he has passed on to this new doctor the age-old interest in the poor and afflicted. Although the new doctor raised his right hand and promised to keep sacredly the Hippocratic oath, he only subconsciously knows the text of his affirmation. The spirit of Hippocrates, of Luke the beloved physician, of Harvey, of Jenner, of Lister, of Osler and of Welch, has become the motivation of the Dafoes and thousands like him who never see their names in print.

The self-imposed two thousand year-old Hippocratic code has become the very fiber of the new doctor's impulse to carry on in high fidelity his consecration to the service of the sick. His cultural and technical training covered almost thirty years of his life. At twenty-seven he received his diploma, and thereafter served one or two years as an intern before starting to exercise his licensed right to practice medicine.

In the mad nineteen twenties the fashionable specialties lured many young doctors into those lucrative fields. In the depressive cycle of the nineteen-thirties the family doctor has been much less embarrassed than the limited specialist, whose practice in many instances disappeared because patients could no longer pay his fees. In this period the family doctor has complained very little, and has cared for his patients regardless of fee, in many cases living on goods given in barter, even in large cities. He and his family have shared hard times before and will do so again. In some regions he refused government aid, while in other regions he now regrets that he has accepted government employment at low or never-paid fees. In large cities his position is more difficult than in small towns or rural regions. The city hospitals are crowded, not only with the normally indigent but also with people who formerly were able to pay for medical care. The doctor works in the hospitals and clinics and often meets his former patients there. He is the only person in the city hospital who works

without pay. Because he has always done so is not a good reason for his continuing to do so.

He works in the hospital for the pay of experience, for the pay of prestige, for the pay of promotion to places of prominence where he may receive the pay of larger responsibilities. He works to learn more about medicine in order to be qualified to learn more about medicine. He is retired for age at sixty-five while he is still a student, and he cannot be made to regret it. The doctor is the servant of the sick, and when he serves the really poor he considers it a priestly privilege. People who are unable or unwilling to pay for medical care crowd free dispensaries to the doors. They are mostly uninterested in the personality of any doctor; their chief interest is in getting something for nothing, and they submit to mass medicine because they must. One hundred and twenty patients in a medical clinic being served by four doctors in two hours means an average of four minutes for each interview, and is very poor medicine. During the same time the same waiting-space holds many other people waiting for other clinics, every one of which is crowded beyond comfortable limits. The clinic nurses and clerks work all day at high speed and are paid for their work. Doctors come and go for two hours or longer, giving their services absolutely free. Some of them are specialists, but most are general practitioners. Although many people are in need of medical service at low fees, and the cost to the city is small because the doctor is unpaid, many doctors would be glad to treat these patients in their own offices for nominal charges, and to give them better care than the hospital, because it would be individualized and unhurried. It would seem to be only fair that doctors as well as other people who work in tax-supported hospitals, or other government institutions, should be paid for their work. At present there is no money to pay them with. Doctors of various kinds who now work for the government receive salaries so small that in ordinary times their positions are unattractive. The government being unable to balance its budget, the prospect of seeing the doctor paid by the state is remote. The family doctor is aware that his status is changing, and desires to be one of the controlling factors in any new program. He justly resents the imposing on him of any compulsory program by nonmedical organizations. He believes that the American Bar would resent the imposition upon it of a program to regulate the practice of the family lawyer in much the same spirit.

The family doctor realizes the value of discussion of every phase of medical service, and is greatly interested in various plans now being put into

experimental operation by county medical societies. He believes that the care of the sick is a medico-sociologic problem, and that all doctors should be organized to attempt a solution. He believes that the old types of individualism will be limited to unhurried study in limited fields involving investigative science.

He disbelieves in the practicability of extending the fields of state medicine, because the burdens of the state already excessively overload the taxpayer. He sees state education in difficulty because it has grown too expensive for the community pocket. He sees thousands of teachers unpaid and out of work, teacher training schools closed, few new teachers appointed; he draws an analogy between state education and state medicine, and believes that a similarly planned system of state operated medical service would be an insufferable load, no matter how honestly it might be attempted. He believes that in any such system expensive bureaucracy would be inevitable, so that the doctor would become a poorly paid servant, his ambition to pursue scientific study would be dulled and general medical service would sink to degraded levels. Such a system cannot escape political manipulation. The legislature which votes the money for it will demand its administration by political officers. It is claimed that public opinion will guide these officers toward wisdom and honesty, but we cannot escape historical precedents which have always shown undue official absorption of the taxpayers' contribution to any public operation. State medicine as we now have it is not attractive to the family doctor; he sees a few brilliant career men who have fought their way to the top, but he believes that most of the rank and file of the lower grades have been lured into the service by the prospect of soup-bone security. The family doctor thinks of state medicine only in terms of relief from financial worries. When the doctor is making a living he forgets it, and turns again to the absorbing interest of giving the best that is in him to his patient; he feels that the government doctors' viewpoint is colored by a salary, and that from their safe vantage point they have lost an understanding of intimate medical problems.

The family doctor is acutely aware that the application of medicine lags behind the science of medicine; he laments the uneven distribution of medical service, even as he is saddened by the tales of inadequate housing and clothing and feeding of some people. The family doctor is in no sense a parasite living well upon the community; he is always willing to share common privation. The profit motive is not large in the doctor's life, but

the incentive to make a living is ever present. Paid research workers represent a very small portion of the medical profession, and the fact that they have not been demoralized by their salaries, often pitifully small, is not an impressive argument for subsidizing the whole medical profession.

The presence of too many doctors, preventive medicine and declining mortality and morbidity as shown by current statistics, cannot be denied as economic factors. Few doctors have acquired wealth from the practice of medicine. Thirty per cent of them are said to be failing to make their expenses. In the light of such a statement the value of the doctors' contribution to the health of the nation is amazing.

The old family doctor of blessed memory is leaving the scene, but his successors are growing,

in effectiveness, and in the interest of the health of the nation deserve the unqualified support of all Americans.

I believe that our people would be responsive to an American health program if the physicians of the country could be inspired to write it. I believe that it should demand the consolidation of all national health bureaus into a national department of health headed by a cabinet officer. I believe that it should strongly preserve the quality of medical care—competently distributed. I believe that the units of health administration should be the states and their political subdivisions where local health needs are known. And I believe that the general practitioner should be supported in his relation to the American family.

303 Tremont Avenue.

CARCINOMA OF THE UTERINE CERVIX*

The Results of Treatment Through 1933, Showing the Value of Supplementary X Radiation

GEORGE VAN S. SMITH, M.D.† AND FRANK A. PEMBERTON, M.D.‡

BROOKLINE, MASSACHUSETTS

EXPERIENCES with carcinoma of the uterine cervix at the Free Hospital for Women have been briefly recorded through 1928.¹ The purpose of the present survey, which takes the place of those now obsolete reports, is to revise the figures for results in the light of longer and much more complete follow up, to embrace in the evaluation those cases seen through 1933, to trace the development of this clinic's treatment and to discuss various pertinent aspects as they arise in the course of compilation.

From May 1, 1876, to January 1, 1934, 997 consecutive patients recorded as having cancer of the cervix were seen or treated. For the purposes of this report it seems proper to omit from detailed consideration 69 of this number who had had their primary treatment elsewhere and were only secondarily seen, treated or given terminal care here.‡

In preparing the material for the previous reports, the authors accepted the clinical diagnoses of cases from which

Presented at the annual meeting of the New England Surgical Society, Boston, Massachusetts, September 29, 1939. From the Free Hospital for Women, Brookline, Massachusetts.

†Assistant professor of gynecology, Harvard Medical School; visiting surgeon, Free Hospital for Women; director, Fearing Research Laboratory, Free Hospital for Women.

‡Clinical professor of gynecology, Harvard Medical School; chief surgeon, Free Hospital for Women; consulting gynecologist, New England Deaconess Hospital, Boston.

Of the 28 patients of the latter group receiving no further treatment at this hospital, 2 were alive thirteen years after primary therapy by radium therapy; the remainder dying before five years. Forty-one received extensive treatment, of whom 34 failed to survive five years, 1 died of recurrence seven years after first therapy and 6 were still on last follow-up, five, seven, seven, seven, ten and thirteen years, respectively, after first treatment.

tissue had not been removed for pathological examination. When patients with only a clinical diagnosis of cervical cancer fail to survive, one tends to assume that the diagnosis was correct because this is the commonest pelvic cancer in women. When however some of these patients are cured the results are of debatable value for statistics without pathological confirmation. In order to avoid the inclusion of these few valueless cases among authentic survivors, and since the diagnoses of those who die remain presumptive (as so well demonstrated by the death certificates of patients who have died away from their place of original diagnosis), 100 cases without pathological diagnosis (75 before and 25 after October 1, 1902) will be evaluated separately.

For the previous papers the authors accepted the pathological reports as given without attempting to review the sections. This raises the question as to how much reliance may be placed upon pathological diagnoses when the microscopic material is no longer extant. We have now taken the stand that a report is not valid unless accompanied by the section or an adequate description of the microscopic picture for it could be argued that the report may have been erroneous, and in general the earlier reports lacked satisfactory descriptions. The 48 cases (33 before and 15 after October 1, 1902) with pathological diagnoses unsubstantiated by section or description will be

†The death certificates of 394 patients covered in this study have been consulted. Cancer was not mentioned in 4 of the alleged causes of death in these being cerebral hemorrhage, purpura myocarditis, pneumonia, shock and kidney trouble. Natural causes, probably heart disease, chronic Bright disease, diabetes, septicemia, phthisis, intestinal obstruction, furia prodiosa with structure and "no cause given." Carcinoma of the cervix was specified in 390 certificates. Of 78 certificates on 27 cancer was mentioned without specification of origin or location. Cancer of the uterus or symphysis were found on 209 and on 15 more. Cancer of uterus, bladder and cervix, of uterus and bladder of uterus and rectum, of uterus and ovary or of uterus and intestines or carcinoma of uterus were found. The remaining 11 or stomach, intestines, sigmoid, rectum, bladder, pelvic organs, hip, intestines and stomach, gilda and bladder, pelvis and abdomen, growth of undetermined nature, in abdomen, malignant disease of pelvis and natural causes, probably cancer.

without pay. Because he has always done so is not a good reason for his continuing to do so.

He works in the hospital for the pay of experience, for the pay of prestige, for the pay of promotion to places of prominence where he may receive the pay of larger responsibilities. He works to learn more about medicine in order to be qualified to learn more about medicine. He is retired for age at sixty-five while he is still a student, and he cannot be made to regret it. The doctor is the servant of the sick, and when he serves the really poor he considers it a priestly privilege. People who are unable or unwilling to pay for medical care crowd free dispensaries to the doors. They are mostly uninterested in the personality of any doctor; their chief interest is in getting something for nothing, and they submit to mass medicine because they must. One hundred and twenty patients in a medical clinic being served by four doctors in two hours means an average of four minutes for each interview, and is very poor medicine. During the same time the same waiting-space holds many other people waiting for other clinics, every one of which is crowded beyond comfortable limits. The clinic nurses and clerks work all day at high speed and are paid for their work. Doctors come and go for two hours or longer, giving their services absolutely free. Some of them are specialists, but most are general practitioners. Although many people are in need of medical service at low fees, and the cost to the city is small because the doctor is unpaid, many doctors would be glad to treat these patients in their own offices for nominal charges, and to give them better care than the hospital, because it would be individualized and unhurried. It would seem to be only fair that doctors as well as other people who work in tax-supported hospitals, or other government institutions, should be paid for their work. At present there is no money to pay them with. Doctors of various kinds who now work for the government receive salaries so small that in ordinary times their positions are unattractive. The government being unable to balance its budget, the prospect of seeing the doctor paid by the state is remote. The family doctor is aware that his status is changing, and desires to be one of the controlling factors in any new program. He justly resents the imposing on him of any compulsory program by nonmedical organizations. He believes that the American Bar would resent the imposition upon it of a program to regulate the practice of the family lawyer in much the same spirit.

The family doctor realizes the value of discussion of every phase of medical service, and is greatly interested in various plans now being put into

experimental operation by county medical societies. He believes that the care of the sick is a medico-sociologic problem, and that all doctors should be organized to attempt a solution. He believes that the old types of individualism will be limited to unhurried study in limited fields involving investigative science.

He disbelieves in the practicability of extending the fields of state medicine, because the burdens of the state already excessively overload the taxpayer. He sees state education in difficulty because it has grown too expensive for the community pocket. He sees thousands of teachers unpaid and out of work, teacher training schools closed, few new teachers appointed, he draws an analogy between state education and state medicine, and believes that a similarly planned system of state operated medical service would be an insufferable load, no matter how honestly it might be attempted. He believes that in any such system expensive bureaucracy would be inevitable, so that the doctor would become a poorly paid servant, his ambition to pursue scientific study would be dulled and general medical service would sink to degraded levels. Such a system cannot escape political manipulation. The legislature which votes the money for it will demand its administration by political officers. It is claimed that public opinion will guide these officers toward wisdom and honesty, but we cannot escape historical precedents which have always shown undue official absorption of the taxpayers' contribution to any public operation. State medicine as we now have it is not attractive to the family doctor, he sees a few brilliant career men who have fought their way to the top, but he believes that most of the rank and file of the lower grades have been lured into the service by the prospect of soup-bone security. The family doctor thinks of state medicine only in terms of relief from financial worries. When the doctor is making a living he forgets it, and turns again to the absorbing interest of giving the best that is in him to his patient, he feels that the government doctors' viewpoint is colored by a salary, and that from their safe vantage point they have lost an understanding of intimate medical problems.

The family doctor is acutely aware that the application of medicine lags behind the science of medicine, he laments the uneven distribution of medical service, even as he is saddened by the tales of inadequate housing and clothing and feeding of some people. The family doctor is in no sense a parasite living well upon the community, he is always willing to share common privation. The profit motive is not large in the doctor's life, but

charged as well on the nineteenth postoperative day her convalescence having been complicated by pelvic sepsis of only moderate severity and died eighteen days later of unknown cause. We have rated this an operative death. There was a postoperative complication in 2 cases in this group a small incisional hernia in a cured patient, and in another a vesicovaginal fistula which healed spontaneously

Three of the patients treated with radium after operation developed fistulas: the vesicovaginal fistula of one was present six months after radium treatment, an attempt at closure failed and the patient died of recurrence four years and five months after hysterectomy. Both rectovaginal and vesicovaginal fistulas, completely inoperable, followed postoperative radium in the other two patients, who were

seven months after operation and two and a half months before death from recurrence.

During this period radium was first employed. The dosage and screening were almost entirely a matter of trial and error, there being practically no precedents on which to base the manner of use. Four capsules of 0.5 mm. of silver containing glass capsules filled with radium salt, the equivalent of 25 mg. of metallic radium each

the long time survivors in this group. One of those receiving radium before operation established a rectovaginal fistula within two months of operation and died of recurrence one year and eight months later.

During these years there was, in general no definite plan behind the administration of radium before and after surgery. Preoperative radium was given in varying doses at varying intervals up to six months in otherwise seem-

made up this hospital's original stock. The only other screening was the rubber used in application according to Graves⁴ that is, the capsules were placed in tandem in rubber tubing for intra-cervical and uterine insertion and plastered to coins and covered with rubber dam for cervical and vaginal abutment. Single doses varied from 600 to 4800 mg. hr., total doses from 600 to 11,200 mg. hr. One to four treatments were given the intervals between them ranging from one week to five months. A few deaths might be attributed to overdosage were it not that only well-advanced cases were given irradiation the more favorable ones being reserved for operation.

ingly inoperable cases, in the hope of rendering them operable. The number of cases so managed was small and the outcomes were disappointing, for the apparently obvious reason that the periphery of the disease was not effectively irradiated. Following operation radium was usually not applied until recurrence was present. It seems that during these early years this element was regarded more as a palliative than as a prophylactic or curative method. Furthermore, the postoperative doses were kept small, 600 to 1600 rarely 2400 mg. hr., for fear of damage to the bladder or rectum. Since radium was not employed immediately after operation unless there was

real doubt as to the completeness of the extirpation, and since it was used later in those cases in which operation clearly had not been successful, a fairer estimate of the results of surgery is obtained by combining the "operation" and "operation, then radium" groups in calculating five-year survivors.

From 1919 to 1923 — 120 Cases (Table 3) Only 1 of the patients submitted to operation developed an incisional hernia. Another reported herself well fourteen months after operation and died of intestinal obstruction one month later. Two other cases of obstruction among the patients of this period are recorded in Table 3. In the radium-treated group, 3 patients developed vesicovaginal fistulas and 3 rectovaginal fistulas. Both types of fistula became established in 2 others. Since all these were terminal cases, it is impossible to estimate how much of the damage was due to irradiation.

During this era the tendency was to reduce the number of doses of radium and the intervals between them. Quite

From 1924 to 1928 — 225 Cases (Table 4) Deaths from radium in hopeless cases are possibly more frequent than recorded, not only because it is difficult in such cases to separate the untoward effects of treatment from those caused by progress of the disease, but also because so often adequate clinical details of terminal courses are lacking. The 2 deaths following radium were due to sepsis eighteen and sixty-five days, respectively, after application. It apparently is simply a matter of good fortune that such outcomes are not more frequent, since a considerable number of patients with pelvic inflammation or dangerously infected cancers, or both, must of necessity be manipulated and irradiated. Two other patients had post-radiation cellulitis and abscess without fatality, although they were very ill for three months and had then only a short period of comfort before succumbing to their cancers. Six patients, who failed to survive five years, came to colostomy for obstruction from the disease three months to two years and ten months after radium treatment. Another obstruc-

a few single treatments were given. It is interesting that 3 of the absolute cures were achieved with a single application each of 2400 to 2550 mg hr and 2 with 3150 and 3375 mg hr, respectively. These were the first favorable cases in which radium was tried in preference to surgery because the patients were poor risks on account of old age, obesity and cardiovascular disease. Large amounts of radium were avoided apparently because of the fear of complications, a fear unfortunately engendered by earlier experiences in which the complications of advancing disease had been mistaken for ill effects of irradiation, and in a few of which the dire effects of overdosage had been observed.

In March, 1922, the hospital's stock of radium was augmented to 225 mg by the addition of two 50-mg capsules and two 12.5 mg needles. There was no change in screening or technic of application, and the postoperative doses remained small. At first there was some timidity about leaving as much as 200 or 225 mg in a patient for more than twelve or fourteen hours, but in 1923 single doses of 200 or 225 mg for twenty-four hours gradually became acceptable.

In this radium-treated group occurred in the patient listed in Table 4 as having died of carcinoma of the rectum nine years and three months after the first treatment — by 4800 mg hr in October, 1924, for frank squamous carcinoma. At five years she was well and examination disclosed no evidence of recurrence. Two years and three months later she returned, having had rectal pain and bleeding for three months. Under anesthesia an annular constriction of the rectum at the level of the cervix was palpated — surface biopsy showed necrotic tissue. Curettage of the endocervix brought away tissue which Dr. Frank B. Mallory termed adenocarcinoma of intestinal origin. There was fixation of the broad ligaments. One hundred milligrams of radium were left in the cervical canal and vaginal vault for twenty-four hours. Two weeks afterward colostomy was made for obstruction, the patient survived for two more years. Although her death is attributed to cancer of the rectum, she may well have had deep pelvic recurrence of her cervical tumor as well.

Still another obstruction occurred, in this case due to an irradiation stricture of the rectosigmoid that manifested itself five months after application to the cervix and uterus.

of 200 mg., screened by 0.5 mm. of silver and 1.0 mm. of brass, for 30 hours. A colostomy was made. Five years and six months later resection of the rectosigmoid and tube anastomosis were performed preliminary to closure of the colostomy. The patient was well ten years and ten months after radiation.

Only one other complication of any severity took place among the 34 patients of this radium treated group (the majority receiving single doses of 4800 to 6000 mg. hr.) who were alive ten or more years later namely a rectal stricture demanding dilatation seven months after 6750 mg. hr. screening as above—the patient since remaining well for ten years. The relative infrequency of serious complications from radium in those patients who are destined to survive is indicated in Table 3 (only one obstruction in the radium group and that after a heavy retreatment for recurrence) and is quite apparent in this larger series.

Five patients of this same group developed fistulas a

25 mg. and two more 50-mg. capsules of radium were added to the hospital's stock in the spring of 1928, making a total of 425 mg. and thus allowing more latitude in the matter of amount and distribution.

From 1929 to 1933—274 Cases (Table 5) Beginning sporadically in October 1930 and with increasing frequency through 1932, radium was administered in two doses of 2400 to 3600 mg. hr. each within a month usually within two weeks of each other for a total of 4800 to 6000 mg. hr., and occasionally even more. Moreover early in 1931 additional screening of 1 mm. of lead was built around the brass-tube applicators with the intention of obtaining by such filtration pure, very short-wave gamma radiation. A comparison of the results from radium alone in Tables 3 and 5 reveals an increase of five year survival from 17 to 25 to 28 per cent during the years when fairly radical changes in technique were being introduced. Nevertheless it is impossible to show that these improved results were not a coincidence or due simply to the em

vesicovaginal sinus appeared one month after radium treatment in an advanced case a rectovaginal fistula opened nineteen months after radium treatment, the patient surviving for twenty-one months afterward another patient's rectovaginal fistula appeared terminally. Two other patients had double fistulas terminally.

There were complications in 2 of the patients submitted to hysterectomy a postoperative hernia, and a vesicovaginal fistula which was closed successfully one year after operation and one year and eleven months before death from recurrence.

Of those patients receiving radium following operation one died after enterostomy for small intestinal obstruction from recurrence another developed double fistulas terminally.

The majority of the radium treatments during the years 1924 to 1928 consisted of a single dose of 200 or 225 mg. for twenty-four to thirty hours, the largest single dose being 6750 mg. hr. By April 1925 applicators of 0.5 mm. of brass (namely tubes of various lengths for carrying the capsules of radium into cervical and uterine canals, and round, flat pillboxes to hold the capsules against the cervix and the vaginal fornices) had been devised and were being put into use, their purpose being to increase screening and to facilitate the placing and holding of the radium. In 1927 a new set of practically identical applicators, but containing of 1 mm. of brass, was put into regular service.^{2,4} The rationale of the brass filtration was to eliminate almost all the so-called "soft" or ulcerative radiation. Four more

employment of large doses of radium, or that they were the result of the use of the applicators and the augmentation of filtration. It can be stated only that the applicators have facilitated the handling and placing of the radium, and that they may have played a part in preventing further complications from irradiation among the survivors. The fact that no late recurrences have yet made their appearance among those treated by radium alone between 1929 and 1933 inclusive, although 19 of the 30 five year survivors have already reached their seventh to tenth year suggests an increased effectiveness of technique.

The main objective of the two-dose plan was to make the second dose more effective by eliminating the local disease with the first for example it is often impossible to locate the cervical canal in cases with everting growths, and even if the canal can be found the disease may be tamponading the surrounding tissues away from the radium. By the time of the second application the condition is nearly always markedly improved—the canal can easily be found and the surrounding tissues have returned to more normal position, owing both to dissolution of the cancer and to better drainage, with alleviation of edema and possibly local infection as well. (The same effect has been accomplished by the use of x-rays before radium, a procedure followed almost consistently at this clinic since the fall of 1937.) Since 1932 the double-dose method has been employed in the majority of cases.

Furthermore, in the spring of 1931 we began using x-ray therapy and by 1932 this was prescribed almost routinely

(exceptions were made for the very earliest cancers), the purpose being to reach areas of disease that were inaccessible to the influence of radium. Dr John W Meachen, roentgenologist to the Free Hospital for Women from 1924 to 1937, heartily co-operated in taking charge of practically all the treatments. Portals of entry varied from 10 by 10 to 20 by 20 cm., target distance was 50 cm., filtration consisted of 0.5 mm of copper and 1 mm. of aluminum, kilovoltage varied from 180 to 200, and milliamperage from 5 to 8. Individual treatments of 400 to 930 r were given, the great majority being of 400 r. Treatments were administered daily for three or four, usually four, days and through three or four, usually four, portals, one or two anterior and two posterior. In general the patients received a series of four treatments, totaling 1600 r, immediately on discharge following examination under anesthesia, biopsy and first application of radium. A second series was given usually about two months after the first. Quite a few patients received a third series, and a number even a fourth series. Actually there was considerable variation, both as to intervals between series of treatments and as to total dosage administered. All patients who received any x-radiation at all are included in the radium and x-ray group, but 21 received 1600 r or less for various reasons and 33 got 2800 r or less, the remaining 121 receiving total doses of 3200 to 8200 r. One hundred and nine patients of the whole group of 154 either had as much x-radiation as they were to get within six months of first radium treatment, or had 3200 r of their total quotas within six months. Twenty-one began to have x-radiation six months to a year after first radium treatment, and 24 began to have x-radiation over a year after first radium treatment. The reason why these patients received their x-ray treatment so late is because immediate postoperative x-radiation had not been adopted at the time of their first admission—they were referred for x-ray from the follow-up clinic on the supposition that this, though given late, might do them more good than harm. We have come to believe that the best procedure is to give all irradiation within a period of four to six weeks.

DISCUSSION

Results of Treatment in the Groups Summarized in Table 5

Amputation of the cervix and irradiation The 2 survivors in this group had had x-ray in addition to radium following operation, at which 1 patient was found to have endometriosis of the rectovaginal septum and early, though grossly apparent, cancer. Because she had prolapse with symptoms, and there being no other palpable evidence of endometriosis or cancer, amputation and plastic were elected. One month later 200 mg of radium was applied locally for twenty-four hours, and within six months three series of x-ray treatments totaling 8370 r were given. A severe generalized pelvic reaction ensued, culminating in a rectovaginal fistula eleven months after operation, in addition to about a year of invalidism. The patient was well and had only mild annoyance from the fistula six years and ten months after amputation of the cervix. Her cancer obviously had been overtreated, but we have wondered whether internal, intangible endometriosis might not have contributed in some way to the unusually severe reaction.

Hysterectomy and irradiation The 4 patients

who received hysterectomy and then irradiation had radium locally within two months of operation, 2 of them received x-radiation also. Complications developed in one of the latter—cystitis coming on thirteen months from the beginning of irradiation, giving symptoms for six months and persisting for a year, during which several dilations of a stricture of the right ureter were performed, there being some hydronephrosis, and a postoperative hernia, repaired early in the sixth postoperative year, by which time the urinary tract was normal.

Radium Of the 4 postoperative deaths in the cases treated with radium alone, 1 was due to peritonitis nine days after palliative application to very advanced disease. One was due to "peritonitis" eighteen days after treatment, the patient having convalesced without mishap for ten days. This death probably resulted from an exacerbation of a pelvic inflammation, although the only palpable abnormality of the internal genitalia at operation was an enlarged uterus. One was due to agranulocytic angina eighteen days after radium treatment. This patient received a transfusion of blood before her first treatment because of fairly marked anemia. There was a moderate postoperative febrile reaction, she was discharged on the 6th day, having had no drugs of the amidopyrine type. Seven days later her terminal illness made its onset in the guise of a "cold." The fourth death was due to alleged pulmonary embolism forty days after radium.

Intestinal obstruction resulting in abdominal cramps and vomiting of two days' duration brought another patient to operation one hundred and fourteen days after radium application. A 25-cm loop of necrotic ileum, the constricted apex of which was freshly adherent in the pouch of Douglas, was excised. Because of shock, no anastomosis was attempted. The patient failed to rally and died three days later. A permit for autopsy was not obtained, although cancer was palpably present.

Three patients in this radium-treated group are recorded as having had rectovaginal fistulas terminally. Only 1 of the 30 five-year survivors of this group had significant complications. Double fistulas appeared fifteen months afterward, while the patient was convalescing from an operation for acute strangulation of a loop of ileum in a left femoral hernia, resection being necessary. By the time further surgery seemed advisable she preferred to carry on with her fistulas. She died of cardiovascular disease at the age of seventy, six years and three months after the first treatment. Three other survivors had radium cystitis coming before the third year and lasting one, six and twelve months, respectively, without ensuing ureteral stenosis.

Radium and x-radiation Though there were in the group treated by radium, then x radiation, no immediate or early deaths after treatment, 3 later deaths are to be laid to complications—and further casualties may still eventuate from the combined treatment as given during that period.

The first fatality took place as follows. Four months after a sequence of treatments, namely 3000 mg. hr of radium, 1600 r 2250 mg. hr and 1600 r, dilatation of the cervix was performed for pyometra associated with severe pelvic pain and fever. A month later dilatation of the cervix for presumed recurrent pyometra disclosed a recto-uterocervicovaginal fistula. The pelvic tissues were very indurated. Cancer was not believed to be present since the primary lesion had been described as about 2 mm. in diameter. Death, apparently from chronic sepsis, ensued one year from the first admission. In retrospect it seems that a colostomy would have been salutary. The second patient's inverting disease had palpably involved the left broad ligament when she was first treated by 4800 mg. hr of radium. Because of pain discharge and induration of the broad ligaments, another local application of 3000 mg. hr was given 6 months later followed during the next three months by two series of x-ray treatments of 1600 r each. The patient was admitted for terminal care one year after the first radium treatment, and died of uremia eight months later. Her entire terminal course seemed to be compatible with advancing disease, even to the appearance of double fistulas a few months before death. At autopsy a special effort to find tumor was fruitless. The kidneys showed acute and healed pyelonephritis there was chronic inflammation of the bladder ureters and rectum. The third death from complications took place five years and three months after the first treatment, consisting of 4800 mg. hr. For one year the patient had been well and examinations had disclosed no evidence of recurrence. Then dysuria pain in the left lower abdomen and tender induration on the left felt by rectum (probably due to irradiation and not to recurrence) led to x-radiation, 3200 r in less than one month. By the third post radium year a vesicovaginal fistula was present, the patient being in other respects well, and examination revealing no other palpable abnormality beyond soft pelvic scarring. Five years and seven weeks after the first treatment, examination and biopsy of the cervix and vulva were performed under anesthesia because of one month's vaginal staining and swelling of the vulva which was whitened, thickened and irritated. Ten days after this procedure uremia made its entirely unexpected onset bilateral ureterostomy was of no avail. Autopsy failed to reveal any evidence of recurrent cancer. There were bilateral uterine stenosis with chronic inflammation bilateral chronic pyelitis and chronic pyonephrosis.

Because of these 3 cases, we are alarmed at the possibility that other deaths in this radium and x-ray group may have been due to treatment and not to advancing disease. On the other hand, the follow-ups have been careful, and known complications before terminal courses were well under way were not unreasonably numerous or severe. The following complications were noted proctitis, 2 cases proctitis with resulting stricture, 1 case, rectovaginal fistula, 4 cases, rectovaginal and vesicovaginal fistulas, 3 cases. Since, however, during the last ten years the majority of patients with apparently advanced neoplasms have been referred

elsewhere for terminal care, we may have lost opportunities for prolonging life and decreasing discomfort by colostomy or nephrostomy for intestinal obstruction or ureteral stricture due to tumor or possibly irradiation reaction. In this connection it was surprising to discover how infrequently uremia had been included in death certificates as a terminal event in carcinoma of the cervix—seven times in 394 certificates. This undoubtedly common omission may be easily explained by the fact that the picture of uremia can be so clouded by cancer cachexia, the use of drugs and the presence of fistulas and a laissez-faire attitude.

It was emphasized above that complications among the five-or-more year survivors without cancer in the groups treated by radium alone were infrequent. The survivors in this radium and x ray group, on the other hand, have suffered an undue share of complications. The finding of some of the otherwise unsuspected damage may possibly be laid to more frequent follow up examinations including studies of urinary and intestinal tracts, but on the whole it seems that the increase of complications must be laid to supplementary x radiation. Furthermore, owing to the difficulty and occasional impossibility of discriminating between recurrent disease and irradiation reaction as regards pelvic induration, some of the damage may be laid to unnecessary as well as necessary (based on biopsied recurrence) retreatment with both radium and x rays. We have been chagrined though pleased, to find 3 patients whom we had referred for terminal care between seven and four teen months after first treatment, well at six to seven years. In cases of doubt we had tended to prescribe further irradiation at the risk of considerable destruction of tissues. In general, patients with irradiation reactions look much healthier than their symptoms warrant, whereas those with recurrence look worse than they feel.

Three deaths in this group we have attributed to treatment. Of the 65 patients alive at five years, 25 had a total of sixty-three complications, of which five were or are serious enough to threaten life, namely, a pelvic abscess resulting in obstruction and colostomy, an incarceration of an irradiated loop of sigmoid in the pouch of Douglas, with partial obstruction demanding operative release, and three functionless kidneys due to ureteral stricture. Fourteen patients had irradiation proctitis, which generally makes itself known six to twelve months after first treatment, from which stricture resulted in 4 (in 1 of whom a rectovaginal fistula broke through six years and five months after first treatment) and rectovaginal fistula in 4. In the remainder the rectal irritation was short lived and not disabling. Thirteen pa-

tients had irradiation cystitis severe enough to give symptoms one to over five years after the start of treatment. A vesicovaginal fistula ensued in 2 patients. The cystitis had been severe and persistent in the 3 patients whose ureters became stenosed, resulting in unilateral functionless kidneys. It was symptomatically only temporary in the others. One elderly patient's ilia showed focal bony resorption, pain on walking and limitation of motion, leading to this finding. Nineteen patients had diffuse scarring of the pelvic tissues, which softened somewhat over a period of two or three years. The scarring does not give specific symptoms, but easily misleads one into prescribing further irradiation. Marked reaction of the skin and subcutaneous tissues of the lower abdomen, buttocks and sacrum was present in most, but not all, the survivors who had received 3200 r or more. It took the form of superficial telangiectasis with thickening of the dermis and scarring of the subcutaneous layer almost to actual induration. Occasional severe itching seemed to be the only symptom. Contrary to expectation, incisions into these devitalized tissues healed satisfactorily.

This enumeration of complications is likely to leave the impression that the survivors following radium and supplementary x-radiation are leading a more or less crippled, unhappy existence, but such is not the case. As we follow them we are surprised at their state of general well-being and at their adjustment to such residual disabilities as fistulas and strictures of the rectum. Feeling so well, they are likely only with some difficulty to be persuaded to undergo the discomfort of continued periodic genito-urinary and lower intestinal investigation.

No rectovaginal fistula resulting from irradiation has been cured in this clinic. The few patients on whom operation was attempted preferred fistula to colostomy. Unless rectal strictures from irradiation are really disturbing, we have found it more satisfactory to leave them alone, since the trauma of dilatation gives more discomfort than the lesion itself—and dilatation does not eradicate it. Our few attempts to repair vesicovaginal fistula from irradiation have only ameliorated the

patients who developed complications. Of 13 patients who developed complications, 1 had a total of 4800 mg hr of radium, 1 had 6000 to 10,200 mg hr of radium, 1 had 6000 to 10,200 mg hr of treatment for biopsied recurrent disease, 8 had received retreatment for recurrence. Only one of the patients had received less than 1600 r of x-radiation, and 1 had received 3200 to 7100 r, as follows:

3200 to 4000 r, 9 cases, 4800 r, 10 cases, 5000 to 6000 r, 2 cases, 6000 to 7100 r, 3 cases. That the remaining 40 survivors in this group have thus far failed to suffer troubles worth mentioning, although they had practically similar treatment, including retreatments, emphasizes again the varied and unpredictable responses of tissues to irradiation.

It seems hardly necessary to make a general summary of the complications described throughout this review or to present their percentage incidences. They were obviously frequent, and probably more often due to cancer than to treatment, except among those who had x-radiation. To avoid complications and at the same time treat cervical cancer adequately is beyond our present abilities. Fortunately, suffering from these disabilities is not so great as would be surmised from their description and enumeration. Accepting a pretty high incidence of complications as inevitable, efforts should be made by careful follow-up to discover them early and prevent serious sequelae, for example, untreated ureteral stricture is the most important of the potentially lethal sequelae, intestinal obstruction being the other really serious possibility, once the danger of severe sepsis is past. We make it a rule when giving patients their next appointments to stress that they report at any time should anything new or unusual develop, in the hope thereby of diagnosing early intestinal obstruction or irradiation cystitis which seems to favor ureteral stricture. We have not yet found ureteral damage in any cancer-free patient who had not had cystitis with symptoms.

During the years covered by this report, periodic examination of the urinary tract had not attained the importance it now holds in the follow-up regime. Damage that could have been avoided has been discovered only among the radium and x-ray group of 1929 to 1933. Ureteral strictures are now being found at an earlier stage—and not often, at that—and have thus far been amenable to cystoscopic dilatation.

That supplementary x-radiation was responsible for the improved results shown in Table 5 is indicated by the following. The series is large enough so as not to be weighted favorably by a chance run of cases with a good result. The disease of 32 (49 per cent) of the 65 five-year survivors had been described as having extended beyond the confines of the cervix. On the other hand, of the "radium alone" groups for 1924 to 1928 and 1929 to 1933, 46 per cent and 33 per cent of the five-year survivors' tumors had been described as inoperable, that is, the number of favorable cases was greater, yet not more than 28 per cent of the patients survived five years, as against 42 per cent in this radium and x-ray series. Another point support

ing the value of supplementary x radiation is that 57 (51 per cent of them had been graded as inoperable), or 47 per cent, of the 121 patients of this group who had received a total of at least 3200 r were alive at five years. Furthermore, it may turn out to be significant that thus far only 1 definite late recurrence has developed (at five years and nine months in a patient whose tumor had been originally classed as advanced to the point of fixation [Table 5]), 33 of the 63 patients well at five years having already reached their seventh to tenth year.

Pyometra

Pyometra is more often a complication of the disease than of treatment. Thus 29 patients had this condition at the time treatment was instituted, and 4 of them developed it again following irradiation. Either by coincidence or because of the combined treatment, 8 patients of the radium and x-ray group 1929 to 1933, developed pyometra during or after treatment. Since only 5 of these 37 patients were alive at five years, pyometra would seem to accompany a poor prognosis, despite the fact that it has not incommoded therapeutic measures to any considerable degree. Treatment has been given either immediately on drainage or within a month, without other mishap. It is perhaps significant that the 5 survivors had had x-radiation, no patient with pyometra before 1930 having lived for five years. (Two had had a preoperative pyometra, 1 a postoperative pyometra, and 2 had had both preoperative and postoperative pyometras.)

Clinical Classification and Pathological Grading

The results in sizable series of consecutive cases of cancer are the really important ones from the point of view of comparison and evaluation of treatments. Hence, in the above compilations, consideration of groups separated out on the basis of clinical rating of the extent of the cancers and on the basis of pathological grading of the degree of malignancy has been practically disregarded. After all, clinical classification is at best fraught with uncertainty, since so many patients with apparently early operable tumors fail to survive, whereas an occasional case with seemingly advanced local growth becomes cured. The not infrequent death from distant metastasis in the absence of any evidence of local recurrence indicates that tumors discovered early enough to be cured by operation or irradiation may spread before yielding to therapy—and often enough have operators encountered pelvic metastases at laparotomy for what had been, on thorough preoperative examination, considered operable, even grossly early, cer-

vical cancers. Likewise disappointing have been attempts to separate groups according to the microscopic picture of the tumor. How can one explain on known criteria late recurrences of microscopically highly malignant cancer after surgery, or cures of inoperable but microscopically well-differentiated, hence presumably radioresistant, cervical tumor by radium? The varied and unpredictable responses of patients and their cancers are so constantly observed as to make it obvious that other unknown factors are involved and that palpable and microscopic grading can be of only little help in evaluating therapy.

Operation versus Irradiation

There would seem to be no longer any argument in favor of operation except for microscopic or near microscopic cancers when other pelvic disease, demanding cure for symptomatic or other reasons (for example prolapse, fibroids, ovarian tumors, endometriosis) or rendering irradiation unnecessarily risky (for example active pelvic inflammation), is present—and except for the uncommon operable cancer that is discovered to be radioresistant before the chance for possible surgical cure has passed. When other pelvic disease is present with more advanced cervical cancer, irradiation risks must be accepted and complications met as they evolve. After all, the good results of surgery have been accomplished in selected cases, but without augmenting total salvages in series of consecutive cases beyond a certain point, whereas the employment of radium and then x-radiation has been followed by a progressive improvement in the total salvage among consecutive cases. In answer to the possible suggestion that the improved results of more recent years may be due to increased percentages of favorable cases, the following figures may be given for what they are worth, namely the percentage of tumors in the various groups described as being confined within the limits of the cervix: 1902 to 1913, 13 per cent; 1914 to 1918, 29 per cent; 1919 to 1923, 26 per cent; 1924 to 1928, 28 per cent; 1929 to 1933, 32 per cent. Thus there has been no significant increase in apparently favorable cases, and furthermore by no means all these were among the survivors.

*Carcinoma of the Cervical Stump**

From Tables 1 to 5, inclusive, have been separated out all the cases of stump carcinoma, a total of 40 for the years 1909 to 1933, inclusive, that is 6 per cent of the pathologically confirmable cases first seen or treated during those years. They are

*Three patients of the secondarily seen or treated group had had vaginal hysterectomy elsewhere nine years, six years, and six months, respectively, before the primary therapy. 1 of the 40 unconfirmable cases first seen or treated in this hospital after 1902, the patient had had vaginal hysterectomy here seven years and ten months before the diagnosis of cervical cancer.

summarized in Table 6 There were no cases of stump carcinoma in this series before 1909 That 5 of the 12 patients who had had their hysterectomy at this hospital returned with stump carcinoma within three years deserves comment They all almost certainly had had early and probably discoverable cancer at the time of hysterectomy Three had had neither biopsy nor treatment of the cervix before operation (1917, 1924, 1925), 1 had had biopsy (the specimen does not show any evidence of cancer, multiple biopsies probably would have disclosed new growth) and cauterization preliminary to operation (1927) and eight months before the diagnosis of cancer, and 1 had had cervical cauterization immediately before hysterectomy (1927) and seventeen months before treatment of her endocervical adenocarcinoma This last patient was not saved, although her tumor

need hardly be stressed that patients with retained cervixes should be followed for long periods, and should be warned to report for examination on the slightest of signs, such as staining or discharge Since carcinoma of the cervix occurs predominantly in women who have been pregnant at one time or another, the question arises as to whether it might be safe to allow the cervix to remain in nulligravidas The answer appears to be that such a procedure is not safe, for 10 (23 per cent) of the 44 cases of stump carcinoma covered above were recorded as nulligravidas

Retreatment

Many of the patients of this whole series received retreatment with radium, some with x-rays also, sometime after their original therapy as described above In the great majority the presence of re

had been apparently localized to the stump, the others are well more than eleven years after cancer treatment In addition to the above two cauterizations performed before the diagnosis of cancer, there was but one other, among all the cases in this report, and that had been done elsewhere seventeen months before the finding of advanced growth† The occurrence of stump carcinoma in such an appreciable number, and the fact that neither cauterization nor repair has been proved to be really prophylactic, make it impossible to avoid the conclusion that, when feasible, complete instead of supravaginal hysterectomy should be performed, and when neither this nor some form of cervical amputation can be undertaken, every effort should be made to rule out cervical new growth, both by thorough curettage of the canal for biopsy and by multiple biopsies from the glandular-squamous junction If a cervix appears diseased enough to warrant cauterization or conization before supravaginal hysterectomy, the biopsies are all the more important It

†Thirteen of all the cases in this report had had the operation of trachelorhaphy 12 (6 at this hospital) five to twenty years before cancer was diagnosed and 1 (not here) less than two years before the diagnosis.

currence was assumed on the basis of the clinical findings That most of these retreatments were futile was proved by the fatal outcomes It is impossible to show that they had even any palliative influence, or that the few patients who turned out to be survivors had not simply had induration from previous irradiation Retreatment for biopsied recurrence most often fails to be salutary, since usually by the time tumor that can be biopsied appears, hopeless spread has occurred Actually only 7 patients, retreated for biopsied local recurrence, have become five-or-more-year survivors, 2 in the secondarily seen or treated group and 5 in the regular series These recurrences were detected four months to four years after first treatment As seen from the tables, retreatment for recurrence after the fifth year of survival has not prevented death

Late Recurrences

We understand this term to mean recurrences after five years in those clinically well at five years after first therapy Eliminating those patients with obvious recurrence at five years, there are left, to

1929, 106 who were well after that interval. Of these, 6 became untraceable, 9 died of intercurrent disease, 17 died of recurrent cancer of the cervix (recurrence assumed in 14, proved in 3) and 3 were alive at ten years but with the disease. Thus 67 per cent of those apparently well at five years were well at ten years. Eight of the late recurrences were in patients treated surgically (all had had squamous-cell carcinoma), 8 in those treated by radium (1 had had adenocarcinoma) and 4 in those treated by both means (all had had squamous carcinoma).

Multiple Malignancy

In the series are only 6, possibly 7, cases which were proved to have had another type of malignancy in addition to that of the cervix cancer of the endometrium at the same time, cancer of the breast at the same time, melanoma of the choroid, diagnosed four years and four months after treatment of squamous cancer of the cervix, cancer of the vulva, diagnosed seven years after treatment of cancer of the cervix, carcinoma of the sigmoid, diagnosed eight years and eight months after cancer of the cervix treated, carcinoma of the rectum, diagnosed seven years and three months after treatment of the cervical lesion, carcinoma of the lower left vagina and left labium minus, diagnosed five years and ten months after treatment of cervical cancer. Since late recurrences of cancer of the cervix are unlikely to involve the lower vagina or labia without evidence of recurrence higher up we are inclined to believe that the tumor in the last case was a new lesion, although microscopically it is indistinguishable from the original sections of the cervix. We conclude, from the various other malignancies recorded in the death certificates, for example cancer of the breast, and from those reported to us, for example cancer of the bladder, that the occurrence of multiple malignancy in this series was somewhat greater than indicated by the above proved cases.

SUMMARY

Of the 997 consecutive cases with a clinical diagnosis of carcinoma of the uterine cervix, seen or treated at the Free Hospital for Women clinic from May 1, 1876, to January 1, 1934, 69 had had their primary treatment elsewhere and 148 (108 before and 40 after October 1, 1902) cannot now be proved to have had the disease. The body of this report is concerned with the remaining 780 consecutive, previously untreated, pathologically confirmable cases encountered from October 1, 1902, to January 1, 1934.

No significant difference in behavior or response to therapy can be discerned between the

adenocarcinomas and the squamous-cell carcinomas.

The percentages of treated cases alive at five years are as follows: October 1, 1902, to 1913, 12, 1914 to 1918, 21, 1919 to 1923, 24, 1924 to 1928, 29, 1929 to 1933, 38. The percentages of treated cases alive at ten years for the same groups to 1929 are 8, 11, 12 and 21. The percentages of treated cases considered cured, that is alive at twelve years, for the same groups to 1929 are 8, 11, 10 and 12 (thus far, since the total number of twelve year survivors for the 1924-1928 group will not be known until January 1, 1941).

Operative mortalities, deaths from intercurrent disease and the occurrence of other malignant tumors, proved and unproved, are included in the charts and discussion.

Complications of the disease and complications from its treatment are described and enumerated in the running discussion. Before the employment of x radiation it appears that complications were most often due to advancing disease. Emphasis is placed on the relative infrequency of serious complications from radium alone in those patients destined to survive.

The best percentage of five year survivors among unselected cases was achieved by the administration of supplementary 200-kv x-radiation — 42 per cent (Table 5) — at the price of an increased number of complications to which death has been attributed thus far in 3 cases. The adjuvant effect of x radiation is even more apparent in the 121 cases of this same group which received at least 3200 r — 47 per cent were alive at five years.

This study brings out again what has already been emphasized by other writers, namely the necessity, as part of the follow up regime, of periodic investigation of the whole urinary tract in all cases, including those with recurrent cancer and especially in those having irradiation cystitis without evidence of cancer.

Clinical classification and pathological grading are omitted as practically useless in the evaluation of therapy.

Since improved results have been associated, first, with the use of radium in a greater number of cases, and then with the employment of supplementary x radiation, it is reiterated that the indications for surgery in the treatment of cervical carcinoma are becoming very much restricted.

The appreciable incidence of carcinomas of the cervical stump in this series (40, or 5 per cent) and the fact that 23 per cent of them were in patients recorded as nulligravidae, re-emphasize the desirability of removing the cervix, even from those never pregnant, when hysterectomy is undertaken, or, if this is not feasible, of taking multiple

biopsies to rule out early cancer, treating the cervix if treatment is indicated for other reasons, and following the patients for long periods after operation, exhorting them to report for examination at the slightest warning sign

Retreatment given to many patients for recurrence is salutary in but a few

In this series, late recurrences are divided equally between patients treated surgically and those treated by radium, and 67 per cent of those apparently free of disease at five years are found to be well at ten years after primary therapy

Thus far there have been 6 unquestionable cases of multiple malignancy in this series

DISCUSSION

DR GEORGE C WILKINS, Manchester, New Hampshire. This paper presents the constantly improving results of thirty years of treatment of carcinoma of the cervix. The improvement is due to a study of the previous results, to a better understanding of the disease and especially to a gradually increasing use of radiation

I note that there was a considerable difference in the radiation dosage during the time the method was being established. This is possibly because there were a number of different men who were giving the treatment.

Evidence is presented that radium therapy is not without troublesome sequelae, and of course we must be very alert to recognize this fact and to treat them. It is sometimes difficult to know whether the symptoms that develop one, two, three, four or five years afterward are due to the radiation or to a recurrence of the disease

The lateness of the sequelae is a peculiar characteristic of radium treatment of cancer of the cervix. It is probable that some of the sequelae may be avoided by proper spacing of the intervals between treatments

We have all been waiting for comparable statistics on cases treated by radium and those treated by radium plus x ray, and the authors of this paper have demonstrated the increase in salvage with the use of deep-therapy x ray added to radium. It must be borne in mind, however, that radium is the predominant therapeutic agency in treating cancer of the cervix, as is shown in this paper and others, there has been a salvage with radium alone in different clinics anywhere from 25 to over 30 per cent, but so far as I know, no one with this disease has been cured by x ray alone

I believe in the use of the x-ray first, as was advocated by Dr Healy in Memorial Hospital. The reasons are that x ray therapy covering a period of four or five weeks will clear up a great deal of the growth, particularly if the latter is productive, and will also clear up infection that frequently accompanies the growth. Then, when one is ready to treat the cervix with radium, it has resumed its normal shape or very near it and is clean. Since we have

been using x ray prior to radium, we have found the application of radium an easier procedure

At the Elliot Hospital from 1920 to the present time, we have had 300 cases of carcinoma of the cervix, not including cervical stump cases. From 1920 to 1934 we had 185 cases, all of which were treated by radium alone. The study is almost completed and only 10 of the cases have not yet been traced. If half of these 10 patients are found to be living five years after treatment, we shall have a 35 per cent five year salvage. They have all been treated in the same way and by only two men, Dr Dwinell and myself. We started treating these cases in one way and have continued without change. We give the patient 3500 to 4000 mg hr of radium for the first treatment, on the theory that this is all the patient can stand without a great deal of irritation. Then in three weeks when the irritation has subsided, we give another dose of 1800 to 2000 mg hr. Curiously enough this coincides with the theory later advanced by Coutard of a twenty-one day periodicity of cell susceptibility to radiation.

DR GEORGE M WATERMAN, Providence, Rhode Island. Dr Pemberton and Dr Smith are to be commended on the excellence of and the improvement in their results. Their paper shows conclusively that x ray must be regarded as an essential factor in treatment. I say this not only because of their excellent results, but also because of the results that are being reported from various other clinics in the country. Dr Meigs has recently published some work that showed excellent results from the use of deep x ray. In his series of 106 cases between 1929 and 1933, before the use of x-ray, the percentage of cures was 28. That is a most excellent showing.

At the Rhode Island Hospital since 1926 we have used a method a little different perhaps than that employed in most clinics. We have adopted the interstitial method of radiation, and have made use of interstitial radiation needles. These are long needles of low radium content, and they are used over long periods of time. We have had 308 patients treated by this method. Of these 97 (31 per cent) survived a five year period.

Two years ago we reported our experience with this method. There were 173 cases with 55 survivals (32 per cent). In a recent series of 135 cases we have had 42 survivals (32 per cent). This shows that we have gone about as far as we can in the use of radium alone in the treatment of cancer of the cervix.

We believe that the method we have used is a safe one. Our morbidity and mortality figures have been even a little better than those of Dr Pemberton and Dr Smith's series of cases treated by radium alone, and we have had no more fistulas or late sequelae than are reported by other clinics. Our incidence of fistula runs a little under 8 per cent, which compares favorably with a series published by Ward and Sackett. With improvement in our use of x-ray therapy we hope for generally better results in years to come.

DR JAMES R. MILLER, Hartford, Connecticut. I hope that Dr Pemberton will be able to bring out in his discussion to just what extent improvement has taken place over all these years. When I first started in practice, one out of ten cases would have been considered operable. Now well over half are considered operable. The one important thing in the treatment of cancer, so far as end results are concerned, is the time at which adequate treatment is begun, and that factor vitates all statistics unless it is taken into consideration.

Dr. J. V. MAUGS, Boston Dr. Pemberton and Dr. Smith are to be congratulated on their figures but I believe that a division of the cases into groups, even if only into operable and inoperable, would be a fairer way to make this report. Certainly the cases seen at the Free Hospital for Women are seen earlier than those at the Pondville Hospital. Therefore the total number of survivors must be greater and the percentage better. Fifty early cases are certainly going to do better than 50 late cases so that division into groups is really essential for comparison. If such a division were made, I am sure that the results in this series would be about the same as in others.

I have been interested at the Pondville Hospital in the study of the urological complications of cancer of the cervix. All patients are examined with the cystoscope by the urologist and studied by intravenous pyelography. The cases under treatment are followed very carefully through their treatment, because occasionally there is a flare up of temperature due to changes in the kidney or ureter. Drainage of the ureter and nephrostomy have been necessary on numerous occasions.

Another question I think important is what to do with cases that do not respond to x-ray and radium. If biopsies are taken throughout treatment, certain patients can be found who do not respond to radiation as demonstrated by microscopic examination. I believe that we should operate on these cases. They do not tolerate surgery well and perhaps we ought to obtain more biopsies during roentgen therapy and decide whether or not the patient is going to respond before we give radium. This method, I believe, would lessen the possibility of fistulas.

Salvage and improvement will come from early diagnosis, recognition of kidney lesions and ability to choose those patients who are likely to respond to radiation.

Dr. HERBERT A. DUFFEE, Burlington, Vermont. My discussion has to do with the prophylaxis of carcinoma of the cervix. Whether or not we consider this disease the result of resting tissue or of irritation from erosion destruction of the carcinogenic zone about the external os has in my experience been 100 per cent efficient in preventing this condition. I believe that one of such procedures as simple cauterization of the zone around the external os, coagulation of that same zone, excision with a conizing knife or a Sturmdorf's operation will prevent almost all true carcinomas of the cervix.

I wish to ask whether anyone here knows of a single case in which carcinoma has developed in a cervix that has been treated by one of the four methods that I have enumerated.

Dr. SMITH. I now have records of 4 cases of carcinoma of the cervix after cauterization. The diagnosis in each case was made more than five years afterward. I do not believe that cauterization should be considered a truly prophylactic measure although in general it seems to have some value as such.

Dr. Miller asked whether an increased percentage of early cases might not have accounted for the improved results in the more recent groups. The percentages of early cases in our five groups are as follows: 1902 to 1913, 13; 1914 to 1918, 28; 1919 to 1923, 26; 1924 to 1928, 28; and 1929 to 1933, 32. This is an increase, but is not commensurate with that of the five year survival rate. Furthermore, these so-called early cases were not all among the survivors.

Dr. PEMBERTON (closing). X-ray dosage is still in the experimental stage. We are now trying voltages from 400,000 to 1,000,000 to see whether there will be better results, and especially whether there is less damage to normal tissue with shorter periods of application. We believe that the method of combining radium and x-ray especially as to whether radium needles and seeds should be used with the central application, is of little importance so long as one attempts to apply a uniform amount of radiation to all parts of the pelvis, in order that a lethal dose may reach the tumor wherever it is.

Our results are better and should be better than those in most other series, because we have included all the private cases and they are as a rule, less advanced than the average. This series represents a cross-section of the general population better than does a series from poor people alone.

Urological follow-up is important because the urological complications are often severe.

As regards cancer developing after cauterization of the cervix, it may take five or ten years for it to appear so that a long period of observation is necessary before an opinion can be given.

The essential point is diagnosis of early cases by biopsy. Last year we biopsied 944 cervixes, and found 8 cases of previously unsuspected cancer.

ESOPHAGOBRONCHIAL FISTULA A RESULT OF A FOREIGN BODY*

Report of a Case

JOHN A. MURTAGH, M.D.,† AND M. DAWSON TYSON, M.D.‡

HANOVER, NEW HAMPSHIRE

THIS case of esophagobronchial fistula, a consequence of a foreign body, is presented because of the resultant unusual circumstances which developed, and because of the relative infrequency of the condition. An investigation of the available literature does not reveal an entirely similar case. Many cases of fistulous communication between the esophagus and the air passages have been reported, but most of them have been the result of cancer or of congenital factors, tuberculosis or syphilis. The present case deserves a report because it definitely illustrates the possibilities of overlooking a foreign body of this type, especially when x-ray studies and an esophagoscopy are negative.

CASE REPORT

J. R., a 50-year-old white man, first presented himself at the Mary Hitchcock Memorial Hospital on October 16, 1938, with a chief complaint of persistent pain in the region of the lower sternum, and inability to take either food or fluids without coughing. Twenty-five days previously, while eating beef broth, something lodged in his throat. He attempted elimination of it by using his fingers, without success. He ate solid food, and succeeded in dislodging the foreign body from its original point of retention and moving it farther into the esophagus. At this time pain developed about the lower sternum. This pain persisted, and on any attempt to swallow was accentuated. Five days later the patient was referred to a hospital, where routine x-rays for a foreign body, with barium in the esophagus, were taken. These were reported negative and he was sent home. During this time the patient had taken only liquids. His normal weight was 158 pounds. He remained at home away from work for about 3 weeks, during which the pain was at times severe and controlled only by sedatives. At some time during this period he developed a cough on the taking of fluids. On admission the patient complained of severe sternal pain and total inability for 3 days to take either solids or liquids by mouth. His weight had decreased to 111 pounds.

Physical examination on admission showed an obviously cachectic, markedly dehydrated man. It failed to reveal anything but the objective evidence of dehydration and weight loss. The vital signs were all normal. Blood Kahn and Wassermann tests were negative. The red-cell count was 4,240,000, the white-cell count 12,900, the hemoglobin 15 gm., and the differential polymorphonuclears, 81 per cent, lymphocytes 13 per cent and mononuclears 6 per cent. The urine gave a + test for albumin. The blood nonprotein nitrogen was 21 mg. per 100 cc., and the blood sugar 80 mg.

Examination by x-ray on admission (Fig. 1) was as follows.

The chest is negative. There is no demonstrable foreign body in the esophagus. On the administration of barium there is no delay or obstruction to its passage through the esophagus. Just below the level of the hilus of the lung, however, a thin tongue of barium is seen to project laterally and forward from

FIGURE 1 Anteroposterior Film of the Chest

This was taken on the day of admission, and was reported to be negative. A lateral view was also negative.

the esophagus into the lung, and coincident with this the patient experienced a severe paroxysm of coughing. Films taken after barium fail to reveal any of the medium in the lungs, but do show a small area of increased density just below the left hilus. The findings are those of esophagobronchial fistula.

Esophagoscopy was done. A thorough investigation of the entire esophagus failed to reveal any foreign body, but demonstrated an area of ulceration and inflammation at the level where the left main bronchus crossed the esophagus. Bronchoscopy revealed an area of marked inflammation and ulceration on the floor of the left main bronchus, approximately 15 cm. from the bifurcation. No foreign body was seen.

The patient was gastrostomized under local anesthesia on October 19, 1938. The day following this procedure the temperature rose to 104.5°F, the pulse to 130 and the respirations to 32. The clinical finding, supported by x-ray, was of bronchopneumonia of the right and left

lungs. There was no evidence by x ray of mediastinal involvement.

Convalescence from this acute phase was without event. The weight on November 10 was 105 pounds. Frequent small feedings with a gastrostomy tube were resorted to, in an endeavor to eliminate the coughing up of gastric contents evidenced, in a small measure, since gastrostomy. Supportive measures, including transfusion, were also employed.

Following complete recovery from the pulmonary infection, Lipiodol was instilled intratracheally and hiling

FIGURE 2. Anteroposterior Film of the Chest

Lipiodol was injected intratracheally with passage of the opaque medium through the fistula into the esophagus. Some of the Lipiodol is in the stomach. There was no evidence of a foreign body.

of the esophagus at a point approximately 2 cm. below the bifurcation of the trachea occurred, further confirming the diagnosis of esophagobronchial fistula (Fig. 2). No foreign body was in evidence.

The patient complained of pain persistently in the region of the lower sternum. Because of this persistent pain and the inability to explain the small area of increased density reported below the left hilus by x ray but without expecting to locate a foreign body esophagoscopy was again done. On re-examination of the esophageal fistula, a very small triangular piece of material was seen protruding from the esophageal wall. This was grasped with a foreign-body forceps and drawn into the esophagus without any tension and removed. It proved to be a bone. The patient's sternal pain immediately disappeared and he was decidedly more comfortable.

Feeding was continued via the gastrostomy for 1 month when esophagoscopy was again done the area of ulcer

tion had disappeared and only slight inflammation was visible. It was learned that the patient had surreptitiously been drinking small amounts of fluid without distress. He was started on small feedings of soft foods and milk without incident. In attempting to take large amounts of water slight irritation occurred, but no coughing. Milk and soft foods caused no distress. The patient was discharged home. He returned in March 1939 at which time bronchoscopy showed a small fistula in the left main bronchus, with no secondary inflammatory reaction. The orifice of the fistula seemed well epithelized, and there was no evidence of the esophageal fistula. Lipiodol introduced intratracheally failed to pass from the left main bronchus to the esophagus.

The patient now carries on his normal activities without any difficulty.

The difficulties presented to the roentgenologist in the determination of the existence of foreign bodies in occasional cases, both in the esophagus and in the lungs, are manifold. In spite of them only a few cases, fortunately, are overlooked. At the time of the initial examination in the case here reported, it is doubtful whether the foreign body had penetrated the esophagus, but this may have occurred without the establishment of the esophagobronchial fistula. At that time no pulmonary symptoms existed. The danger of disregarding the patient's story in spite of negative roentgen findings, no matter how thoroughly or capably done, is evident. The precariousness of giving an unqualified negative opinion with an existing history of foreign body is well known to every competent roentgenologist. In this case the foreign body was not demonstrable in a thorough investigation by x ray on two occasions, although in the second instance a fistula had been established and the patient's general condition was obviously poor. That the bone may have been overlooked when the patient was first examined by esophagoscopy is again a possibility, although the location of the bone at the subsequent procedure does not indicate this. That the patient did not develop mediastinal involvement or succumb to the pulmonary infection, or develop a residual pulmonary complication, is fortunate. The location of the foreign body, invisible in the left main bronchus and with only a small bit protruding into the esophagus, is unusual. The rapidity with which the esophageal end of the fistula closed is of interest.

SUMMARY

An unusual case of esophagobronchial fistula, resulting from the lodging of a bone in the esophagus and subsequent penetration of the left main bronchus, is reported and briefly discussed.

ESOPHAGOBRONCHIAL FISTULA A RESULT OF A FOREIGN BODY*

Report of a Case

JOHN A. MURTAGH, M.D.,† AND M. DAWSON TYSON, M.D.‡

HANOVER, NEW HAMPSHIRE

THIS case of esophagobronchial fistula, a consequence of a foreign body, is presented because of the resultant unusual circumstances which developed, and because of the relative infrequency of the condition. An investigation of the available literature does not reveal an entirely similar case. Many cases of fistulous communication between the esophagus and the air passages have been reported, but most of them have been the result of cancer or of congenital factors, tuberculosis or syphilis. The present case deserves a report because it definitely illustrates the possibilities of overlooking a foreign body of this type, especially when x-ray studies and an esophagoscopy are negative.

CASE REPORT

J. R., a 50-year-old white man, first presented himself at the Mary Hitchcock Memorial Hospital on October 16, 1938, with a chief complaint of persistent pain in the region of the lower sternum, and inability to take either food or fluids without coughing. Twenty-five days previously, while eating beef broth, something lodged in his throat. He attempted elimination of it by using his fingers, without success. He ate solid food, and succeeded in dislodging the foreign body from its original point of retention and moving it farther into the esophagus. At this time pain developed about the lower sternum. This pain persisted, and on any attempt to swallow was accentuated. Five days later the patient was referred to a hospital, where routine x-rays for a foreign body, with barium in the esophagus, were taken. These were reported negative and he was sent home. During this time the patient had taken only liquids. His normal weight was 158 pounds. He remained at home away from work for about 3 weeks, during which the pain was at times severe and controlled only by sedatives. At some time during this period he developed a cough on the taking of fluids. On admission the patient complained of severe sternal pain and total inability for 3 days to take either solids or liquids by mouth. His weight had decreased to 111 pounds.

Physical examination on admission showed an obviously cachectic, markedly dehydrated man. It failed to reveal anything but the objective evidence of dehydration and weight loss. The vital signs were all normal. Blood Kahn and Wassermann tests were negative. The red-cell count was 4,240,000, the white-cell count 12,900, the hemoglobin 15 gm, and the differential polymorphonuclears, 81 per cent, lymphocytes 13 per cent and mononuclears 6 per cent. The urine gave a + test for albumin. The blood nonprotein nitrogen was 21 mg per 100 cc, and the blood sugar 80 mg.

Examination by x ray on admission (Fig 1) was as follows.

The chest is negative. There is no demonstrable foreign body in the esophagus. On the administration of barium there is no delay or obstruction to its passage through the esophagus. Just below the level of the hilus of the lung, however, a thin tongue of barium is seen to project laterally and forward from

FIGURE 1 Anteroposterior Film of the Chest

ance of the face is characterized by erythema, papules and pustules. Comedones may be present but do not typify the disease. Increased oiliness may be present but is not constantly so.

Rosacea is frequently associated with blepharitis, conjunctivitis, keratitis and corneal ulcers. The blepharitis is usually a dry scaly, chronic disturbance, occasionally associated with erythema and edema. The other three ocular manifestations are more commonly acute and recurrent. The corneal ulcers may lead to vascularization of the cornea and scarring, and to serious impairment of vision.

One of the outstanding features of the treatment of rosacea, as I see it, is its potent effect in preventing recurrence of conjunctivitis, keratitis and corneal ulcers. The ophthalmologist is best qualified to treat the acute attacks referable to the eye itself. The dermatological program of care has a natural place in aiding the ophthalmologist in the management of the acute attack but it has a more decided effect in preventing recurrences of these ocular attacks. The probable explanation of the favorable effect on the eye of the treatment of rosacea lies, in my opinion, in the fact that the disease and its ocular sequelae are linked together on the basis of a common factor of infection, the numbers of which on the skin are reduced by dermatological care. In other words, rosacea, as well as the associated blepharitis, conjunctivitis, keratitis and corneal ulcers, is probably due to cutaneous infection by *Pityrosporum ovale* (bottle callus of Unna, spore of Malassez) by *Demodex folliculorum* or by some other organism of the nature of a fungus, yeast or perhaps a bacterium.

It is not the purpose of this paper to enter the controversy of what is the precise nature of the factor of infection in rosacea, but merely to express the opinion that the disease behaves clinically like a skin infection and that successful treatment may be outlined accordingly.

Moore, Kile and the Engmans² have made recent studies of the relation between *P. ovale* and seborrheic dermatitis. They succeeded in growing this organism in pure culture from typical cases of the disease. In the scales the fungus was demonstrated in mycological preparations. Injections of a pure culture of this organism into the skins of patients already suffering from the disease produced lesions indistinguishable from seborrheic dermatitis. Inoculations of a pure culture of this fungus into normal-appearing scalps resulted in the development within a week of itching and marked scaliness at the site of the inoculation. Injections made in the same way into the skins of rabbits and guinea pigs produced a dermatitis characterized by scaling and crusting. Pathological studies of areas of experimentally produced dermatitis revealed the presence of *P. ovale*.

If rosacea is merely a manifestation of seborrheic dermatitis, and if *P. ovale* is its cause, one may justifiably speculate in regard to a possible etiologic relation between this organism and rosacea.

Ayres and Anderson³ have studied an association between the presence in the skin of *D. folliculorum* and the occurrence of rosacea. Though admitting the frequent presence of *D. folliculorum* in normal skins, and hence realizing the impossibility of fulfilling Koch's postulates, they believed, nevertheless, that this organism represented an important etiologic factor in certain cases of rosacea. They found moderate to large numbers of *D. folliculorum* in superficial pustules and follicular scales in 50 out of 63 cases examined. All but 3 of their patients in a series of 69 improved or recovered completely following the use of strong antiparasitic ointments and the daily use of soap and water. Ayres and Anderson obtained these excellent results in their first series by the use of an ointment containing Betanaphthol, sulfur and balsam of Peru. In a larger series, later, they obtained equally good results with Danish ointment.

The above lines of observation and reasoning indicate that rosacea is due to infection of the skin. It may, however, be due to lowered resistance to a type of skin infection to which we are all exposed. This lowering of resistance is probably governed by many and varied influences, such as focal infection, lowered gastric acidity, excess of carbohydrates in the diet, nervous and emotional states and other mechanisms which have been studied intimately by Stokes⁴ and his associates. Brilliant and extensive studies of this disease have been made by them, and they have given us much to think about in reference to interpretation and management. The limited scope of this paper does not permit a complete review of Stokes' outstanding contributions. However, a scholarly knowledge of the subject and the ability to treat the disease with the utmost effectiveness would require more than passing familiarity with his work.

Stokes and Beerman⁵ have taken a viewpoint of strong skepticism in reference to the work of Ayres and Anderson concerning rosacea and *D. folliculorum*. They repeated this work and could not substantiate the laboratory data but found sulfur to be of value in treatment. They obtained much improved results, however, by combining sulfur with constitutional treatment.

Regardless of the theoretical considerations and the arguments of these two schools of thought, a spectacularly successful program of care can be organized purely on the basis of rosacea conceived as a type of infection primarily in the scalp but capable of invading eyebrows, eyelids, conjunctiva

and cornea, as well as the central portion of the face and cheeks

Among the best pharmaceutical preparations for local application to the face and scalp are sulfur, ammoniated mercury and yellow oxide of mercury. When used on the scalp these chemicals seem to work better if combined with salicylic acid and *Liquor Carbonis Detergens*. When used on the face, sulfur and ammoniated mercury both seem to behave better if combined with zinc oxide. Yellow oxide of mercury, corrosive sublimate and boric acid are particularly well suited for the eyelids, and one of these three should be so employed as a matter of routine in all cases of rosacea associated with ocular complications. All formulas of value in treating the scalp are generally of equal effectiveness in treating the eyebrows, but are often too strong, if not dangerous, for eyelids, because of proximity to the eyes. All formulas useful in treating blepharitis seem to be of value in treating the eyebrows.

A program of treatment suited to the average case of rosacea and its ocular complications may be outlined according to the scheme indicated below. A high percentage of cases tolerate this program, and about 80 per cent or more recover under it. Patients not tolerating sulfur usually tolerate ammoniated mercury and recover with similar speed. A sample program may be described as follows:

1 The most important step of all is a local application to the face. Sulfur is generally regarded as the best. Walker prefers sulfur lotions, but my experience is that sulfur ointments seem to be very much more effective*. Ayres and Anderson recommend Danish ointment, which is a valuable remedy but is probably more apt to produce dermatitis than are other sulfur mixtures. The following 10 per cent sulfur formula is usually successful:

| | |
|------------------------------|-------------|
| ℞ Sulfur (precipitated) | 3 00 |
| Zinc oxide ointment (U.S.P.) | |
| Aquaphor (Duke) | āā ad 30 00 |

This should be applied each evening to the forehead, cheeks, nose and chin, or merely to the affected areas. In some cases weaker concentrations (5 per cent) are tolerated better, whereas in others it is necessary to employ concentrations as high as 20 or 40 per cent.

If sulfur is not well tolerated, it may be replaced in the same formula with ammoniated mercury in concentration of 5 to 20 per cent. Mercury in this form is very effective.

If the patient tolerates neither sulfur nor am-

moniated mercury, other antiseptic formulas can be attempted, but less favorable results may be anticipated. *Metaphen* (in oil), betanaphthol, *Balsam of Peru* and yellow oxide of mercury are substitutes worth trying.

2 Most dermatologists agree that treatment of the scalp is an essential part of the plan of management in rosacea. At the start an ointment should be used, along with frequent shampoos. Later the ointment may be applied less frequently and gradually replaced by a suitable scalp lotion.

A good scalp ointment is the following formula, devised by Foerster, of Milwaukee:

| | |
|-----------------------------|-------------|
| ℞ Salicylic acid | 2 00 |
| Sulfur (precipitated) | 2 00 |
| Solution of coal tar (N.F.) | 8 00 |
| Aquaphor (Duke) | |
| Lanolin | āā ad 60 00 |

An excellent scalp lotion has been developed by Udo Wile, of Ann Arbor, Michigan:

| | |
|-----------------------|-----------|
| ℞ Mercury bichloride | 0.26 |
| Chloral hydrate | 24 00 |
| Spirit of formic acid | 20 00 |
| Castor oil | 4 00 |
| Menthol | 4 00 |
| Alcohol (80 per cent) | ad 360 00 |

3 Hygienic instructions are generally given in regard to maintenance of cleanliness of combs, brushes, towels, washcloths and pillow slips. (These hygienic measures are logical and seemingly helpful, but my experience is that they are not absolutely essential.)

4 The hands should be kept strictly away from the face. The habit of leaning on the fist or palm of the hand is forbidden. The impulse to scratch, rub, pick at or squeeze lesions is forbidden. These habits may lead to severe factual scarring, and they may interfere seriously with the patient's power of recovery.

5 Other measures of value include oral administration of calcium, hydrochloric acid and vitamin D. Calcium may be taken in the form of the gluconate, a teaspoonful to a half-glass of water thirty minutes before each meal and at bedtime. Dilute hydrochloric acid (U.S.P.) should be taken in doses of 20 to 60 drops in fruit juice or milk, sucked through a glass straw during meals. The effective dose of vitamin D varies between 8000 and 100,000 U.S.P. units. For best results, calcium, hydrochloric acid and vitamin D should all be taken at the same time, thus providing intensive calcium therapy. Both hydrochloric acid and vitamin D have an effect in improving the absorption of calcium. In addition, the administra-

*The use of ointments in treating rosacea is a situation quite in contrast with that encountered in ordinary acne, wherein all greasy preparations must be used in a restricted sense or else avoided entirely.

tion of hydrochloric acid tends to correct the hypochlorhydria often seen in rosacea and other skin diseases. Occasionally, vitamin D alone seems to be very effective treatment.

6. The diet should be restricted in carbohydrates. Excessive eating should be avoided, and food should be masticated slowly. Abstinence from vasomotor foods, drugs and gastric irritants is advised. In regard to the intake of tea, coffee, alcohol and condiments, moderation or abstinence is usually advisable.

VERRUCAE

Warts, though externally located, generally superficial and readily accessible, can be an exasperating disease from the standpoint of both doctor and patient. At a recent meeting of the Academy of Dermatology in Philadelphia, about fifty physicians met in an informal group and discussed warts as a therapeutic problem, and seemed to be in agreement that in many cases the problem is a difficult matter. This resistant group of cases will tax to the limit the therapeutic resourcefulness of even the most versatile specialists.

On the other hand, warts may be regarded as the easiest of diseases to treat. Often enough they disappear spontaneously. Bloch¹¹ was able to cure 44 per cent of cases of common warts and 88 per cent of cases of juvenile warts by suggestion therapy alone. It is certainly true that a high percentage of all types of warts will respond in a predictable period of time to all methods of treatment now in use, especially x-ray therapy and surgical diathermy. One can say with assurance that there is an answer to the wart problem in every case: patience and persistence and repeated application of the best measures will invariably conquer the disease. At the beginning, the patient should be warned of the limitations of our methods of treatment, so that he will not give up in despair in case first attempts fail, yet he should be reassured quite emphatically, so that he will benefit fully from the psychotherapeutic value of the treatment employed.

The types of warts most commonly encountered in practice include verruca vulgaris, verruca plana juvenilis and verruca plantaris. All these varieties are considered to be due to a virus infection, and all respond to the standard forms of treatment with a satisfactory degree of promptness and completeness.

Though warts are due to a transmissible type of infection, the source of the infection causing them in any given case is usually impossible to trace because of the extraordinary latent period, which may be as long as twelve to twenty months.¹⁰

Verruca vulgaris may occur anywhere on the

skin. The appearance is so characteristic and so familiar as scarcely to merit description. In children, particularly between the ages of twelve and fifteen, these warts may be quite numerous, sometimes exceeding a hundred or more. In adults, warts are as a rule less common and much less numerous. The tongue, eyelids, scalp, penis, hands and all other areas of skin may be involved.

Verrucae planae juveniles, otherwise known as flat or juvenile warts, are flesh-colored, slightly raised, flat-topped, rounded or angular papular lesions. They are generally multiple, often quite numerous and are commonly distributed on the face, neck, hands, wrists and knees. They tend to spread in a linear manner along lines of scratch.

Verruca plantaris occurs most commonly at the points of pressure of the ball of the foot. Usually the plantar wart presents a soft, light-brownish core and a hard, calloused rim. This type of wart serves to increase friction at points of pressure, and increases the tendency to callus formation to a considerable extent. It is not uncommon to find a rather small plantar wart surrounded by a very large zone of callous reaction. Plantar warts are undoubtedly contracted from walking on surfaces previously trod by people carrying the disease. Avoidance of the habit of walking barefooted in bedroom and bathroom will prevent many cases. The incidence in gymnasiums and schools can be reduced by careful examination of the feet and appropriate treatment of infected cases, forbidding the patients to use showers and swimming pools until a certificate of cure has been obtained.

There is no prophylactic treatment for warts. The best that can be offered is treatment of each wart as it appears.

The treatment may be directed along many different lines, including internal remedies, injections, local applications, electrodesiccation and radium and x-ray therapy. The virus is probably not limited to the warty area, but undoubtedly inhabits surrounding areas of skin. If a wart is removed by surgery or surgical diathermy, the site may easily be invaded again from the surrounding skin. Autoinoculation in this way takes place more commonly after ordinary surgical procedure than after electrodesiccation. The use of a good antiseptic such as iodine before and after operation tends to reduce recurrences.

As previously mentioned, Bloch advocated treatment by suggestion, and thus cured 88 per cent of juvenile warts and 44 per cent of common warts. Since he succeeded in proving beyond question that warts may be cured by the power of suggestion, he thus provided an explanation for the success

of methods of therapy in common use among the laity, such as rubbing the wart with a piece of raw meat and burying the meat under an apple tree on a moonlight night, rubbing the wart with a cut apple licked with the tongue, and conjuring among Negro healers

This work by Bloch represents a startling contribution. He is an able physician whose integrity is not to be doubted. Space does not permit a complete review of his work, but those who doubt the feasibility of his conclusions are referred to his original paper in German. His experiments were carefully controlled, and they are very convincing.

Bloch's usual method of suggestion therapy consisted of the following procedure. The eyes of the patient are bound and he sits with his hands on an electrically controlled vibrating machine. No electrical currents of any nature enter the body from this apparatus, and possibly the chief power of suggestion lies in the noise made by the machine. A drawing is made of the parts involved and the locations of all warts are marked on it. The warts are painted with a supposedly inert coloring fluid such as saffron, methylene blue or eosin. The blindfold is then removed. It is impressed on the patient that so long as any trace of color is still visible the warts are not to be touched, and that he must be careful about this in washing himself each day. He is then assured that the warts are quite certain to disappear. Other methods of suggestion therapy were employed in occasional cases, and sometimes Bloch relied chiefly on verbal suggestion.

Following Bloch's suggestion treatments, hemorrhages into warts often occurred, and complete disappearance without scarring would then take place in four to eight weeks. Many cases recovered following suggestion therapy after having failed to respond to x-ray, cautery, mercury, arsenic, acids and other ordinary methods. A number of cases successfully treated by suggestion were of many years' duration, and the response to treatment was so prompt as to exclude the possibility of spontaneous recovery.

A phenomenon commonly encountered in treating large numbers of warts consists in the disappearance of all warts after the treatment of only a few. This may be a phenomenon of suggestion therapy, or else the destruction of a few warts may release into the blood stream protein substances that stimulate immunity.

Protiodide of mercury in doses of $\frac{1}{6}$ gr., three times a day, and magnesium sulfate in doses of 10 to 30 gr., three times a day, are among the most popular of the internal remedies. They are usually of a low grade of efficacy. Perhaps they exert

benefit by power of suggestion, as may also be the case with injections and other forms of therapy.

Bismuth employed as an intramuscular injection is used frequently in the treatment of warts. Without doubt, it is efficacious in a modest percentage of cases of common, flat or plantar warts. Practically all forms of antisiphilic therapy, including mercury, neoarsphenamine and sulfarsphenamine, have been reported to be of value.

Electrodesiccation under novocain anesthesia is probably the most effective of all types of treatment for warts. If it is applied skillfully, excellent cosmetic results may be obtained. If warts treated by this method tend to recur, they should be promptly retreated by the same technic. Recurrences following a second treatment are very rare.

X-ray therapy in the treatment of common and plantar warts is usually employed in a dosage of 300 to 1500 r (a few daring therapists employ 2000 to 3000 r in a single dose). Before treatment, the wart is shaved down and shielded with leaded rubber. Within one to three weeks the wart may become a little hypersensitive and slight erythema may be detectable. Disappearance usually takes place within four to eight weeks. If the wart fails to respond, a second treatment, with a dosage dependent on the initial dose and the reaction to it and given by the same technic, is considered permissible. If the second treatment fails, further x-ray therapy is usually contraindicated, particularly if large doses were previously employed. The percentage of cures from x-ray therapy may be increased by the use of two or three applications of bichloroacetic acid during the first four weeks after x-radiation.

The results of radium therapy are about the same as those obtained by x-ray, and the principle of treatment is essentially the same. X-ray is used much more commonly and has tended to supplant radium.

It is appropriate to give a note of warning in regard to the x-ray or radium therapy of plantar warts. The chief contraindication to either form of radiation therapy is a history of previous use of either, even when the interval has been as long as eight or ten years. The serious accidents occasionally seen in the treatment of plantar warts by x-ray are encountered almost invariably when such treatment has been repeated two or more times. No radiation therapy should be given until an accurate record of previous therapy has been made available. Good judgment then employed in regard to total dosage should prevent the disasters that sometimes occur. The factors which enter the estimation of dosage include age of patient, thickness of skin and depth of pigmentation,

degree to which wart is trimmed, and amount of previous dosage as well as reaction to it. Even after using the finest judgment, idiosyncrasy can not be avoided.

In the treatment of flat warts, simple local applications, such as ammoniated mercury, salicylic acid, sulfur and resorcin, are often efficacious. Mercury protiodide given by mouth is in common use, and bismuth injections represent a valuable form of therapy. One of the most effective methods consists of touching each visible wart lightly with a desiccating needle, repeating the procedure about once weekly, and following each treatment with a small dose of x-ray (35 to 75 r) to the affected areas — not to each wart.

In the treatment of warts the dermatologist occasionally encounters patients who refuse or should not have x-ray or radium therapy and who, for reasons of convenience, object to a minor operation with surgical diathermy. These cases are best handled by the use of acids, such as bichloroacetic. If this is applied skillfully, large numbers of warts may be treated painlessly and successfully in a few visits. This method, however, gives a lower percentage of cures than does x-ray therapy or surgical diathermy, and the degree of destruction is more difficult to control, keloidal scars occasionally result.

ALOPECIA AREATA

Alopecia areata is a disease that bears an ominous prognosis, not fully deserved. This bad reputation is derived from those rather exceptional cases which fail to respond to any form of treatment, and go from bad to worse despite heroic efforts on the part of both doctor and patient. It is far closer to the truth to state that most patients recover either spontaneously without treatment or coincidentally with treatment. Every dermatologist probably sees in his career scores of cases with complete recovery while under observation.

In regard to prognosis, Walker and Percival¹ stated "The prognosis is good. If a patient is under forty, the physician may confidently predict recovery. The exceptions are so few that he may cheerfully take the risk of them. Even in those cases where every hair on the body has disappeared, dogged perseverance in treatment is usually rewarded."

As a rule, the diagnosis of alopecia areata is readily established on the basis of simple inspection of the skin. The characteristic appearance is that of a sharply circumscribed patch of complete alopecia, associated with no inflammatory changes. The bald area is smooth and glossy, and essentially normal except for the absence of hairs. At the margin of these patches there are loose,

broken-off hairs, which show on removal an attenuation of the bulb, resulting in an appearance which has given rise to the term "exclamation point hair." These patches may coalesce to form a wide variety of patterns, and may extend until every hair on the body has disappeared.

Rarely, alopecia areata involves the bearded area of the face and spares the scalp. In these cases the diagnosis is not so readily established and is often missed.

Alopecia areata must be carefully distinguished from the patchy alopecia of early syphilis, ring worm, lupus erythematosus, alopecia seborrhoica of the patchy type and pseudopelade. The differentiation is easy except in the case of syphilis. Routine Wassermann, Hinton and Kahn tests are indicated. All three should be done.

The true etiology of alopecia areata is unknown. There is evidence of a transmissible factor of infection. Bowen² reported an epidemic in a girls' home where, after the introduction of a case, 63 out of 69 girls were affected. Two or more cases may occur in a single family. Thun, Sabouraud and many other workers thought they were able to isolate micro-organisms of etiologic importance. The most convincing evidence regarding communicability, however, comes from the numerous authentic reports of epidemics.³⁻⁵ Of interest are the toxic and neuropathic theories of etiology.

Every case of alopecia areata should undergo the traditional studies, including general medical examination, routine blood and urine tests, search for foci of infection and a determination of the basal metabolism. The basal metabolic rate is often lowered, and if so, thyroid medication should be given as a part of the general program of care. In other respects, also, the treatment should be guided by and based on general medical investigations.

In many cases the outstanding clinical findings are evidences of severe nervous and emotional stress and strain. Often these nervous and emotional components are beyond the influence of ordinary medical care. Recovery may take place under treatment by physical and chemical agents, despite the absence or failure of psychotherapy.

In my experience, most of the cases with only one to three or four patches of alopecia areata of the scalp clear up completely within three months on a program including general medical care, all the vitamins in large doses, a diet high in sulfur and other minerals but restricted in carbohydrates, daily applications of an ointment containing oil of cade, sulfur and salicylic acid, and ultra violet light in large doses administered every week or two.

A valuable prescription is the following

| | |
|----------------------------|----------|
| R _x Oil of cade | 12 00 |
| Sulfur (precipitated) | 6 00 |
| Salicylic acid | 3 00 |
| Rose water ointment | ad 60 00 |

The above ointment may be applied daily to the bald areas

Cases of alopecia areata of more widespread distribution are as a rule more difficult to treat, more unpredictable and more given to recurrences

Other recommended forms of treatment include iron, arsenic, pilocarpin by mouth and stimulating and antiparasitic local applications, such as resorcin, turpentine, cantharides, phenol, tar, iodine, sulfur and mercurials

An excellent scalp lotion for use in alopecia areata is the following

| | |
|-------------------------|-----------|
| R _x Phenol | 4 00 |
| Tincture of cantharides | 15 00 |
| Castor oil | 4 00 |
| Alcohol (95 per cent) | ad 120 00 |

This may be applied with friction to the affected areas once or twice daily

ALOPECIA SEBORRHOICA

The common seborrheic type of alopecia is a prevalent source of anxiety and distress to large numbers of men and to a lesser number of women. The response to treatment in young women is usually gratifying, but no reputable dermatologist will make extravagant claims as to what may be accomplished in men of any age. In treating the disorder in men, there is general agreement that much can be done to retard the rate of hair loss, particularly if it is associated with considerable evidence of seborrheic dermatitis. Men showing alopecia without anything more than a slight detectable scaling type of seborrheic dermatitis probably have important etiologic influences of the nature of nervous and glandular disorders. It is quite clear that, at the present time, the methods of ameliorating the neurogenous and endocrinological factors are not sufficiently effective to permit any convincing accomplishments so far as hair growth is concerned. Cases showing the common frontal, bitemporal and vertical types of baldness with little or no evidence of seborrheic dermatitis may be interpreted as having the idiopathic type, and they have a less favorable prognosis than those with the clear-cut seborrheic type.

In spite of the differences between the idiopathic and the seborrheic types of alopecia, the treatment of both is about the same, and is based on the technic and principle involved in the treatment of seborrheic dermatitis of the scalp. The lotions

and ointments useful in treating seborrheic dermatitis are also useful in treating cases of alopecia of the common type (see section on rosacea). There is evidence that vitamin A is of value to hair growth and that vitamin D may be effective in treating seborrheic dermatitis. Hence, any rich source of these vitamins, such as cod-liver oil or haliver oil, has a theoretical as well as a time honored place in the general program of care. The diet should be rich in sulfur, as provided by eggs and meat, and rich in all other minerals, as provided by milk. Fruits, vegetables, meat, eggs and milk should be taken in liberal amounts, but moderate reduction of sweet, starchy and fatty foods is indicated. Instructions regarding cleanliness of combs, brushes and hatbands, and barber shop precautions, are given. Ultra-violet light therapy every week or two in sufficient amounts to sunburn the scalp seems to hasten the disappearance of inflammatory changes, occasionally stimulates slight degrees of regrowth of hair in men, and seems to be immensely effective in stimulating regrowth in young women.

The use of scalp exercises and massage has a place in the management of the common type of baldness, but is not recommended until all evidence of inflammatory disturbances has been eradicated.

In regard to the part played by covering the scalp with a hat, writers have called attention to the following effects: exclusion of air and sun shine, pressure on and partial occlusion of the vascular network supplying the scalp and hypersecretion of sweat. These effects represent only one part of the general etiologic interplay, but in spite of the reasonableness of considering hat wearing a cause of baldness, it must be acknowledged that discarding the hat seems to have no very clear-cut influence on hair growth.

Recent work concerning the use of the male sex hormone in treating various types of genital hypoplasia proves beyond doubt the ability of this hormone to stimulate hair growth in regions such as the face, axilla, chest, pubis and extremities.¹ It is well known that in patients with Fröhlich's syndrome, eunuchs and other types of hypogonadism there may be abundant growth of hair on the head with scant growth on the bearded areas of the face, chest and pubis. It is a well-established fact that extreme degrees of the common type of hair loss may be associated with abundant hair growth on the face, chest and pubis. One of my patients observed sudden onset of baldness of the scalp coincident with great increase of hair growth on the chest and pubic area. These observations would lead one to conclude that the mechanism of hair growth on the scalp is regulated by influences quite different from those at work in other

regions of the body. Certainly the common type of alopecia is usually associated with ample evidence of sufficient secretion of the male sex hormone. In myxedema, the hair of the head and elsewhere is dry, brittle and sparse. Its growth is retarded and it tends to fall out. Haircuts are necessary only at very long intervals. The scalp is dry and scaly.¹²

These thoughts would lead one to suspect that hair loss of the common type may have, at least in part, a glandular basis. Perhaps the pattern is an increased output of male sex hormone and a reduced output of thyroxine. At any rate, the glandular mechanism remains unknown and no therapy on this basis is available. Administered to the skin in ointment form, the male sex hormone is absorbed into the blood stream and exerts a general physiologic action, along with intensive action on the tissues locally. I have employed testosterone propionate ointment locally to the scalp in several cases of the common type of alopecia after clearing up the element of seborrheic dermatitis. In these cases, the total period of treatment has not been sufficient to warrant conclusions as to its efficacy. No effects in either retarding or accelerat-

ing hair growth have been observed. The use of testosterone propionate is merely suggested as an endocrine approach deserving further clinical investigation.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26121

PRESENTATION OF CASE

A seventy-four-year-old housewife was admitted to the hospital complaining of jaundice.

The patient had enjoyed good health until eleven months before admission when she had developed painless jaundice, clay-colored stools, dark urine and intense pruritus. These symptoms fluctuated in intensity but never completely disappeared. A few normally dark stools were passed, but at no time did she experience any real nausea, vomiting, pain, chills or known fever.

Throughout this eleven-month period she had a good appetite, ate well of fruits, vegetables, milk, eggs and carbohydrates. Her diet consisted of little meat, however, and she eschewed fats and butter on her doctor's orders. She had lost 40 pounds, and weighed only 128 pounds on entry.

For two months before admission she was mildly constipated, receiving relief by taking cathartics (Epsom salts) every third day. Two weeks before entry she had a transient attack of indigestion and regurgitated a small amount of recently ingested food, but there were no other symptoms.

The patient had been under constant medical attention during the present illness. She had been placed in an outside hospital for a short interval, nine months before admission, where all studies done were reported as "negative." No special diagnostic procedures were performed since that time. She remained at home cooking and caring for one of her seven children until she was admitted.

The remaining family, marital and past histories were non-contributory.

Physical examination revealed a remarkably well-preserved, cheerful, co-operative woman, who had dry jaundiced skin. She showed evidence of weight loss, but was in no discomfort. The peripheral blood vessels were "markedly sclerotic." The apex of the heart was percussed at the midclavicular line in the fifth interspace. A precordial systolic murmur was best heard at the apex, and the blood pressure was 170 systolic, 82 diastolic. The lungs were normal. The abdomen was soft and lax, without evidence of ascites. The liver edge was not felt. A questionable, ill-defined, non-

tender mass was palpated in the right upper quadrant. The remainder of the physical examination was essentially negative.

The temperature, pulse, and respirations were normal.

Examination of the blood showed a red-cell count of 4,130,000 with 11.5 gm of hemoglobin (photoelectric-cell technic), and a white-cell count of 9100 with 81 per cent polymorphonuclears, the stained smear was negative. The urine showed a specific gravity of 1.008, with no albumin, sugar or bile. The sediment contained a rare red blood cell, 8 white blood cells and 20 epithelial cells per high-power field. The icteric index was 60, and the van den Bergh 8.8 mg per 100 cc., with a biphasic reaction. The serum nonprotein nitrogen was 23 mg per 100 cc. Four stool examinations were both guaiac and bile negative.

Roentgenograms of the gall bladder (Graham method) showed that it was not visible after the patient took the dye. The interpretation was rendered difficult by the presence of gas shadows in the large bowel, but the test was believed to be positive.

On the fifth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. HENRY H. FAXON: The history states that the urine showed no bile. Is that correct?

DR. TRACY B. MALLORY: Two urine examinations were bile negative.

DR. FAXON: That is confusing in the light of the other laboratory data.

The story comes down to that of a seventy-four-year-old woman in whom jaundice was the outstanding, and only complaint that we have to consider seriously. The nonprotein nitrogen, blood count and so forth were not remarkable. So far as the gastrointestinal tract goes, there are only two minor points mentioned. One is the fact that on one occasion she regurgitated food. It does not say whether there was any blood in the vomitus, nor whether it contained bile. The other reference is to the large bowel, it was noted she had increasing constipation. Some increase in constipation might be expected in the absence of bile in the intestinal tract. It is of significance that the stool examinations were guaiac negative.

It is important to establish whether or not hers was a true obstructive jaundice, but the presence of an increased icteric index, a positive van den Bergh test and clay-colored stools seems to me to establish this fact definitely.

What then are the factors we might consider that could have caused the jaundice of which she complained? I do not believe it is a jaundice of the

hemolytic type, because of the age of the patient and the absence of any history or findings of infection. There is another possibility—that of cirrhosis of the liver or intrahepatic disease. The liver was not enlarged, no spleen was felt and she had no ascites, hence it would seem that this possibility could likewise be excluded. The third possibility is that of gallstones. Gallstones, as an incidental finding, are very common in elderly people at postmortem examination. However it is my impression that it is not common to find silent gallstones giving rise to abnormal signs with out some antecedent story of at least mild biliary complaints. It would be unusual, but not impossible, without an antecedent story to find a patient with a stone in the common duct. The gall bladder x-ray studies are of very little help to us. Apparently the Graham test was positive, but the report is evasive in stating that the interpretation was rendered difficult by the presence of a gas shadow. Another dubious point in relation to the gall bladder that leaves us in some doubt is that the physical examination states that a questionable ill-defined mass was palpated. In a woman who had lost so much weight and with an abdomen noted as soft and lax, I should have expected that were she to have an enlarged gall bladder the examiner would have made it out without the doubt that is here expressed.

The last possibility as a cause for the jaundice is cancer, and with this consideration one is faced with the problem of whether or not it was a metastatic or primary manifestation. I think it is unlikely, with the story of no enlargement of the liver, that the steady increase in jaundice would arise from metastatic disease unless the metastasis happened to be in such a strategic position that it blocked the common bile duct. Primary cancer in the region of the bile duct, the head of the pancreas or the ampulla of the duodenum could cause biliary obstruction and jaundice, and it seems to me that the absence of pain and the progressive nature of the jaundice—although there were intermittent spells where she did get some bile through into the large bowel—indicate that she may well have had cancer of the head of the pancreas or common bile duct. If you look at the story as a whole the course is a steadily progressive affair, despite the transient periods of improvement. To be able to say whether the primary cancer was in the head of the pancreas or in the bile ducts, is almost impossible. If I assume that the questionable mass was an enlarged gall bladder, cancer would fit in with the old dictum of Courvoisier's law, namely, that the development of jaundice with cancer gives a large

gall bladder, whereas if stones are responsible the gall bladder is not distended.

I have deliberately and perhaps very unwisely skipped over the feature of absence of bile in the urine. I rather upbraid myself for having asked at the opening of the discussion if this finding was correct, for I was sure there was going to be some bile in the urine. It is confusing to find that at two examinations this was not present. I suspect that the surgeon when he explored this case was in some doubt as to the nature of the lesion. It is my impression he feared he might encounter cancer but hoped he would find a solitary stone to explain the jaundice. My first diagnosis is cancer of the head of the pancreas or bile ducts, and my second choice, an obstructive gallstone.

DR. MALLORY: Does anyone else care to hazard an opinion?

DR. FAXON: Would someone like to explain to me the absence of bile in the urine, in the presence of the story and chemical findings that are given here.

DR. JOHN STEWART: My guess would be that it was an erroneous observation.

DR. FAXON: One determination might be erroneous, but the two reports bother me.

DR. STEWART: The foam test is certainly open to differences in interpretation by various observers.

DR. MALLORY: It may have been observed by artificial light.

DR. J. H. MEANS: I might mention a case that bears out what Dr. Faxon has said about intermittent obstruction in cancer of the head of the pancreas. We had a patient who had a clinical story of stone, with intermittent jaundice. He got over it and then had a recurrence of the jaundice. He was young and we thought that cancer was out of the question. He was explored and cancer of the head of the pancreas was found.

DR. LANGDON PARSONS: In spite of the fact that this patient had lost 40 pounds, she felt perfectly well and was admitted to the hospital simply for relief of the itching from her jaundice of eleven months' duration. In our line of reasoning we followed much the same train of thought that Dr. Faxon has. I was helped enormously by Dr. Stewart, who had made observations, on the basis of vitamin K and liver function studies, relative to determining whether we were dealing with carcinoma of the head of the pancreas or with obstructing gallstones. I think he might be asked to comment.

DR. STEWART: It may be of interest to tell you a little about the prothrombin values in this case, as determined by the method of Warner, Brink

hous and Smith A level such as this woman had when she entered, namely 72 per cent of normal, is rarely or never seen in jaundice due to carcinomatous obstruction, presumably due to the fact that as a rule with obstruction due to carcinoma there is little or no escape of bile salts into the gastrointestinal tract, hence no decrease in absorption of vitamin K. This determination is definitely of some help in diagnosis, particularly when it is a question of deciding between carcinomatous obstruction of the bile duct or obstruction due to stone. Patients with obstruction due to stone show levels in general from 15 to 20 per cent higher than do patients with obstruction due to carcinoma. On the other hand, the determination is of no particular value in differentiating intrahepatic disease, so-called catarrhal jaundice, from jaundice due to stone in the common duct, but in this particular case the finding of 72 per cent, coupled with the other elements in the clinical picture, made us more optimistic about the diagnosis than Dr Faxon was.

PREOPERATIVE DIAGNOSES

Choledocholithiasis
Carcinoma of gall bladder?

DR. FAXON'S DIAGNOSIS

Carcinoma obstructing the common duct?
Choledocholithiasis?

ANATOMICAL DIAGNOSIS

Choledocholithiasis

DR. PARSONS She had a small sclerotic gall bladder, not much bigger than my thumb, and a dilated common duct with a stone measuring 3 cm in diameter impacted in the duct at the papilla. Nothing was done to the gall bladder. The common duct was drained, and she made a perfectly good recovery.

PATHOLOGICAL DISCUSSION

DR. MALLORY I can add nothing to what has already been said. The essential thing in any case of this sort is not to allow one's pessimism to prevent exploration.

CASE 26122

PRESENTATION OF CASE

A sixty-nine-year-old unmarried woman was admitted to the hospital complaining of indigestion.

She had first been seen by a physician eleven days before entry at the request of her landlady and much against the patient's will. At this time

the patient was quite weak and unco-operative so that no well-defined story of her illness could be obtained. As near as could be determined she had been suffering from indigestion over a period of twelve or fifteen years. The landlady stated that during the three years preceding the initial examination she had eaten most of her meals in her room and had complained bitterly about the food regardless of its quality. She had retired from teaching five months before entry and since that time had failed rapidly and hardly ever left her room. She had lost considerable weight, and for three weeks had been confined to bed because of profound weakness. For some time she had regurgitated everything ingested. At the time of her first examination the regurgitated material was *coffee colored and contained small particles of undigested food*, it was later discovered that she had drunk coffee a short time before. She coughed frequently and raised considerable sputum, but it was impossible to determine how long this had been going on. She insisted that there was no pain or tenderness anywhere. Bowel movements had always been more or less costive.

Physical examination by the physician who had been called showed her to be extremely emaciated, weighing about 80 pounds. She stated that her usual weight had been 125 to 130 pounds. The patient was very unco-operative, unreasonable and abusive in her language. There was well marked arcus senilis. Oral hygiene was poor. There was no engorgement or visible pulsation of the neck veins. The heart was normal in size and shape, and the sounds were of good quality, there were no murmurs. The blood pressure was 90 systolic, 65 diastolic. The breath sounds showed diminished intensity throughout both lungs, but percussion was normal and no rales were heard. The abdomen was soft and doughy. There was no tenderness, and no masses could be felt. Pulsations of the aorta were easily detected. There was no peripheral edema. The skin was dry and flabby, and there was evidence of considerable weight loss. Hospitalization was advised immediately, but the patient refused. Her condition continued unchanged during the succeeding ten days up to entry. For two or three weeks prior to her admission she was unable to take any solid food, and much of the liquid ingested was regurgitated.

Examination at entry was unsatisfactory, but the findings were essentially those of the previous examination except that many scattered coarse rales and rhonchi were audible throughout both sides of the chest. One examiner felt a mass in the umbilical region about the size of an orange, which appeared to be fixed and moderate

ly firm but not tender This was not corroborated by others.

The temperature was 101.0°F, the pulse 110, and the respirations 24

Examination of the urine showed a specific gravity of 1.022, with a slight trace of albumin The sediment contained large numbers of white blood cells and a rare red blood cell The blood showed a red-cell count of 4,500,000, with a hemoglobin of 80 per cent. The white-cell count was 11,300 with 90 per cent polymorphonuclears The sputum was purulent and contained tubercle bacilli A stool examination was negative.

X-ray examination of the chest showed diffuse hazy mottled dullness involving the upper two thirds of the lung fields. Within the dullness in the left upper lobe there were several large areas of rarefaction having the appearance of cavities A gastrointestinal series showed marked dilatation of the entire esophagus, and during the fifteen minutes of fluoroscopic observation only a trace of barium entered the stomach This was insufficient for satisfactory examination, but there did appear to be considerable irregularity of the fundus and separation of the fundus from the dome of the diaphragm

The patient became considerably weaker, and her condition progressively worse. Four days after study another chest film confirmed the previous findings and in addition demonstrated round shadows at the bases. Her condition was steadily downhill, the temperature fluctuated between 97.0 and 101.0°F and the pulse between 80 and 120 He died on the fourteenth hospital day

DIFFERENTIAL DIAGNOSIS

DR. THOMAS V. URBY Certain aspects of this case seem rather obvious, and others less apparent First of all, I believe that this patient must have been suffering from cerebral arteriosclerosis, as witnessed by her lack of co-operation, unreasonableness and abusive language. Her bitter complaint about food, regardless of the quality, was doubtless at least in part on this basis, and we would like to believe that this was also the reason for her refusal to seek medical aid until she had become very weak.

The patient had tubercle bacilli in her sputum, and the x-ray description of her chest is certainly consistent with advanced pulmonary tuberculosis This diagnosis alone could well account for progressive weakness and loss of weight as well as chronic indigestion over a period of twelve to fifteen years. However, pulmonary tuberculosis would not cause the more recent symptom of regurgitation of food or, of course, the gastrointestinal

x-ray findings. It becomes necessary to make a further diagnosis of a lesion of the upper gastrointestinal tract, which had produced a marked dilatation of the esophagus as well as a deformity in the region of the fundus of the stomach. Marked dilatation occurs only in long standing lesions, such as cardiospasm, which is by all odds its commonest cause. Unfortunately, simple cardiospasm does not explain the picture in the fundus. Also, had cardiospasm been present all these years we should expect an earlier onset of regurgitation. Carcinoma of the fundus would explain the considerable irregularity seen in the x-ray films, as well as the five months rapid downhill course and the coffee grounds vomitus. But there are several inconsistencies. First of all, the dilatation of the esophagus was much more marked than is usually seen in carcinomatous obstruction. There was no anemia, though dehydration may make the red-cell count apparently higher than it really is. The guaiac test on the stool was negative, though it was, of course, only a single examination. Apparently there was not the increased constipation that we usually see in cancer of the stomach. Moreover, we should seriously consider tuberculosis of the stomach. It is well known that it occurs in the fundus, and that it can be a long-standing affair. It could not only explain the years of symptoms, but also the marked dilatation of the esophagus in the absence of true cardiospasm. The lack of anemia and the negative guaiac tests on the stools are probably more consistent with this diagnosis than with cancer.

Tuberculosis of the stomach may be of the sclerosing type, the ulcerative type or the hyperplastic type. The ulcerative type is the one most commonly found in the fundus. It is usually accompanied by involvement of the peritoneum and the regional lymph nodes, a fact that would not only explain the hard mass between the fundus and the diaphragm, but also give a reasonable cause for stricture of the lower end of the esophagus. This type of tuberculosis would seem to me, then, to be the most likely gastric lesion, though a hyperplastic tuberculous lesion should also be considered.

One or two other diagnoses suggest themselves. Extreme weakness and a low blood pressure with known tuberculosis raise the question of involvement of the adrenal glands. I cannot rule out this possibility, but there is insufficient clinical data for a diagnosis. The weakness, after all, could be explained on the basis of the pulmonary and gastric infections. The blood pressure, though low, is not so low as that usually seen in Addison's disease. There is no mention of pigmentation

We may conjecture about the mass in the umbilical region felt by one examiner. It could represent tuberculosis involving lymph nodes, peritoneum or intestines, or all three.

Finally, the many scattered coarse rales and rhonchi heard at the time of admission and the round shadows at the lung bases four days later suggest the aspiration of food and subsequent aspiration pneumonia, secondary to the obstruction of the esophagus.

CLINICAL DIAGNOSES

Carcinoma of the stomach
Pulmonary tuberculosis

DR URMY'S DIAGNOSES

Cerebral arteriosclerosis
Chronic pulmonary tuberculosis
Tuberculous ulcer of the fundus of the stomach,
with regional involvement of the peritoneum
and lymph nodes and secondary dilatation
of the esophagus
Aspiration pneumonia

ANATOMICAL DIAGNOSES

Pulmonary tuberculosis, advanced
Tuberculosis of bronchial lymph nodes
Pulmonary embolism and infarction
Bronchopneumonia
Cardiospasm
Pleuritis, chronic, fibrous
Arteriosclerosis, moderate, coronary, renal and
aortic.

Emaciation
Operative scar thyroidectomy

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY. An accurate and detailed history is always the most important part of any differential diagnosis, and when this is impossible to obtain, as in the case of the present irritable and unco-operative patient, one is at a grave disadvantage. Like the clinicians who took care of her in the hospital, Dr Urmey sought an organic lesion to explain her symptoms suggesting a tuberculous ulcer whereas they had thought of carcinoma. No organic lesion of the esophagus or stomach was found, however. The esophagus was quite dilated, measuring 4 cm in diameter, and its walls were markedly thickened, averaging about 5 mm. The cardiac orifice was constricted but could, nevertheless, be dilated. There was no ulceration or any suggestion of tumor. Sections through the wall of the esophagus showed a moderate degree of displacement of muscle fibers by connective tissue and some inflammatory infiltration. These are the usual postmortem findings of a case of cardiospasm. It is very probable that her entire fifteen years of "indigestion" was due to functional obstruction of the esophagus.

The lungs showed a very advanced, progressive tuberculosis with many foci of caseation and of calcification. A surprising finding was a fairly large pulmonary embolus, which completely obstructed the artery to the right lower lobe. All the other organs were small and atrophic in proportion to her severe emaciation.

OLD MEN PLANT TREES

ATTENTION is particularly drawn to the article by Mr Lowell, which appears in this issue of the *Journal*. Considering the demands that are now being made on all aspirants for an opportunity to practice medicine, this sane and unemotional estimate of the educational possibilities of the average medical student and of the physical and mental attributes of the practicing physician must appeal to all those doctors who are not blinded by prejudices engendered because of the lack of breadth of view inherent in their jobs. The author, his distinguished educational background and his wide humanity, all preclude the possibility of serious dispute of his remarks by anyone other than his intellectual equal. It is a masterpiece of understatement to say that such a requirement will

materially limit the scope of any debate. Let each doctor, whether a practitioner or a teacher, answer as well as he can the questions propounded by Mr Lowell, and then re-evaluate his own contributions to the care of patients and the teaching of medical students. Then he will no longer be impressed by how much he knows and how much the student should learn, but rather by how much he has failed to grasp and by the good fortune that makes students physiologically incapable of remembering more than a small part of what is taught them until such time as they are able themselves to winnow the wheat from the chaff.

HOME CANNED FOOD

WITH the rising cost of foodstuffs and the emphasis on conservation of foods that inevitably accompanies war, there will undoubtedly be an increase in the practice of home canning. This widespread and economical procedure is one that is none the less fraught with a certain amount of danger. No kitchen is equipped with the apparatus for sterilization and control of the packing processes to the extent that commercial establishments are. In foods canned commercially under the present requirements the danger of botulism is virtually nil. In home-canned foods, on the other hand, botulism is somewhat of a problem even now.

Clostridium botulinum is a widespread organism and owing to its anaerobic nature grows in air-tight containers. The spores of the bacillus are resistant to heat, and unless a high temperature is maintained over a sufficient period of time to kill them, the organism will begin to grow in the canned food and elaborate toxin.

There have been over two hundred sporadic outbreaks of botulism in this country, most of these have occurred on the West coast, although practically every state has had them. In most instances the infection has come from canned vegetables, rarely from meat products. This may be due to the greater frequency of vegetable canning in the home. Non acid foods, such as beans, are more dangerous than tomatoes or other acid vegetables.

In Europe most of the outbreaks have been traced to contaminated sausage. Fortunately, although the spores are resistant to heat, the toxin itself is easily destroyed.

Two procedures can be recommended for the prevention of botulism. The first is to destroy all cans of food that show evidence of bulging or which are noted to contain gas bubbles or on opening have a rancid odor or slushy appearance. Secondly, all home-canned vegetables should be thoroughly heated to boiling before use. These precautions are so simple and so easily carried out that there can be virtually no excuse for the occurrence of this disease.

MEDICAL EPONYM

BILHARZIASIS

The first description of the clinical picture of this infestation appears in an article by Dr. Theodor Bilharz (1825-1862), then resident in Cairo, in the *Wiener medizinische Wochenschrift* (6:49-52 and 65-68, 1856), entitled "Distomum haematobium und sein Verhältniss zu gewissen pathologischen Veränderungen der menschlichen Harnorgane [*Distomum haematobium* and Its Relation to Certain Pathologic Changes in the Human Urinary Organs]." A previous article, chiefly of zoological and anatomical interest, had appeared in the *Zeitschrift für wissenschaftliche Zoologie* (4:52, 1852-53). The translation of a portion of the article is as follows:

The symptoms of the disease which is always chronic in nature, as will be shown, are partly the well known one of catarrh of the bladder, partly peculiar and indicative of the presence of *Distomum haematobium*—a persistent sensation of pressure and heaviness in the hypogastric region—at times violent burning or colicky pain—tenderness in the bladder region—frequency of micturition—hematuria, usually small in amount, but persistent and frequently recurrent—admixture of mucus in the urine. The catheter often meets with rough areas which may be confused with urinary calculi, but which may easily be distinguished by their immobility and soft consistency. It is often possible by simultaneous rectal examination to feel these areas between the finger and catheter.

The most reliable and easiest method of diagnosis is microscopical examination, which usually reveals numerous ova in the mucous sediment of the urine and especially in the little clumps of blood cells.

SEPSIS AND THROMBOPHLEBITIS FOLLOWING FORCEPS DELIVERY

Mrs. A., a thirty-one-year-old para III, entered the hospital on February 5, 1938, because of scarlet fever at home; she was at term but not in labor.

The family history was negative. She had had the usual children's diseases and pneumonia. The tonsils and adenoids had been removed when she was a child, and the appendix in 1924. Catamenia began at twelve, were regular with a thirty-day cycle and lasted three or four days. The last period was April 12, 1937, making the expected date of confinement January 19. The first pregnancy was terminated at twelve weeks because of pernicious vomiting. The second pregnancy went to term and resulted in a living child weighing 10 pounds, 3 ounces; the convalescence was uneventful. The present pregnancy had been normal.

Before entering the hospital a Dick test was negative. The period of incubation had been passed, and a Dick test repeated after entry was again reported negative.

Two days later, February 7, she started in labor and was delivered by forceps of a child weighing 10 pounds, 15 ounces. There was more than the normal amount of bleeding after delivery but not enough for transfusion.

On February 9, forty-eight hours after delivery, the temperature rose to 104.0°F, and the pulse to 150. A consultation was held, and blood and uterine cultures were taken. The blood culture showed no growth after twenty-four hours. The uterine culture was positive for hemolytic streptococcus. Sulfanilamide was started immediately. She maintained a temperature of 103.0 to 104.0°F for approximately twenty-four hours, when it came down to 102.0, on February 13 it had dropped to 100.0. However on February 13 she had a chill and the temperature rose again to 102.0°F, but came down to 99.0 on February 14. The pulse rate dropped to 100. The temperature and pulse gradually rose again until February 17 when the temperature was 104.0°F, with a pulse rate of 140 to 150.

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

used there for two days. On February 17 given a direct transfusion of 500 cc. of. On February 18 there was edema of the tenderness in groin and induration of the c wall, and the clinical picture was diag a pelvic thrombophlebitis. It was be at the fever might be due to the sul le, so the drug was discontinued. Fol mission of the drug, the temperature steadily until it reached 98.0°F on Feb- with a pulse of 80 to 90. The tempera ained normal for two days, then rose to with a corresponding rise in the pulse iter three days; it again reached normal remained until her discharge on March 18. lamide was administered in the follow ings: February 10, 70 gr., February 11, February 12, 70 gr., February 13, 90 gr., February 14, 60 gr., February 15, 40 gr., February 16, and February 17, 80 gr.

Laboratory work was as follows: Febru- white-cell count 16,000 and red-cell count , February 12, white-cell count 18,000 and count 2,800,000, February 14, white-cell 100 and red-cell count 2,980,000, February e transfusion, white-cell count 16,800 and count 3,200,000, and after transfusion, il count 11,000, red-cell count 4,160,000 oglobin 75 to 80 per cent, February 19, il count 10,500, February 21, white-cell ,200, February 23, white-cell count 20,000 cell count 3,970,000, February 28, white it 7700, red-cell count 4,270,000 and hemo 5 per cent, March 4, white-cell count l-cell count 4,270,000 and hemoglobin 75

ient. This is a case of puerperal infection n hemolytic streptococcus origin, which forty-eight hours after a forceps delivery r or not the scarlet fever at home had g to do with the disease is of course ques-

The temperature and pulse rose abrupt sultation was held and sulfanilamide thera ediate instituted. Following a gradual the temperature and pulse again rose, this incident with a definite pelvic thrombo- . The temperature reached normal in the hours and stayed normal for two days, gain, with a corresponding rise in pulse d finally reaching normal after a three-day ource, where it remained until discharge. reatment was conservative throughout. Sul ide was given for eight days and then dis ed. The thrombophlebitis was treated by leation of poultices to the lower abdomen : patient was kept in bed for two weeks

after a normal temperature had been reached and maintained. She was a very sick woman and while it cannot be definitely said that sulfanilamide affected the cure, it certainly is probable.

This case illustrates the proper handling of uterine infection. At the onset of the fever, cultures should be taken from the uterus and the blood. Sulfanilamide should be given whenever streptococci are proved to exist. This work can best be carried on with the assistance of a trained bacteriologist. In this case the uterus was left alone. The occurrence of thrombophlebitis proves that sulfanilamide does not necessarily prevent complications, and the use of heat rather than cold is the routine generally accepted at the present time.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions of the Medical Postgraduate Extension Courses have been arranged for the week beginning March 24

BERKSHIRE

Thursday March 28 at 4.30 p.m., at the Bishop House of Mercy Hospital, Pittsfield. Head and Spine Injuries. Instructor Walter R. Wegner. Harry G. Mellen, *Chairman*.

BRISTOL SOUTH (Fall River Section)

Tuesday March 26, at 4.30 p.m., at the Union Hospital, Fall River. Cardiovascular Disease. Eleven important questions about heart disease and their answers. Instructor Edward F. Bland. Howard P. Sawyer *Chairman*.

FRANKLIN

Thursday March 28, at 8.15 p.m., at the Franklin County Hospital, Greenfield. Syphilis in Pregnancy and the Offspring. Instructor Francis M. Thurmon. Halbert G. Stetson *Chairman*.

HAMPDEN

Thursday March 28 at 4.00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8.15 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Common Problems in Neurology. Indications for lumbar puncture. Instructor H. Houston Merritt. George L. Schadt, *Chairman*.

HAMPSHIRE

Thursday March 28 at 4.15 p.m., in the Nurses Home of the Cooley Dickinson Hospital, Northampton. Gonorrhea in the Female. Instructor Alonzo K. Paine. Warren P. Cordes, *Chairman*.

MIDDLESEX SOUTH

Thursday March 26 at 4.30 p.m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Syphilis in Pregnancy and the Offspring. Instructor C. Guy Lane. Dudley Merrill *Chairman*.

NORFOLK

Thursday March 28 at 8.30 p.m., at the Norwood

Hospital, Norwood. Pneumonia Instructor
Maxwell Finland. Hugo B C Riemer, *Chairman*

NORFOLK SOUTH

Monday, March 25, at 8 30 p m, at the Quincy City Hospital, Quincy Common Problems of Neurology Indications for lumbar puncture. Instructor T J C von Storch David L Belding, *Chairman*

PLYMOUTH

Tuesday, March 26, at 4 00 p m, in the Nurses' Home of the Brockton Hospital, Brockton Pneumonia. Instructor Earle M Chapman Walter H. Pulsifer, *Chairman*

SUFFOLK

Thursday, March 28, at 4 30 p.m, in John Ware Hall, Boston Medical Library, 8 Fenway, Boston. The Use of Drugs in the Treatment of Childhood Infections Instructor John A. V Davies. Reginald Fitz, *Chairman*

DEATH

ADAMS—ZABDIEL B ADAMS, M.D., of Brookline, died March 16 He was in his sixty sixth year

Dr Adams attended the Massachusetts Institute of Technology and received his degree from the Harvard Medical School in 1903 From 1903 to 1905 he was house surgeon at the Boston City Hospital From 1905 to 1906 he was assistant surgeon at the Children's Hospital and from 1906 to 1924 orthopedic surgeon at the Massachusetts General Hospital, serving as chief of the orthopedic service the last two years From 1925 until his death he served as consulting orthopedic surgeon at the Lakeville State Sanatorium in Middleboro

For six years Dr Adams was instructor in orthopedic surgery at Harvard Medical School and associate in anatomy there from 1919 until his death

Among his affiliations were fellowships in the Massachusetts Medical Society and the American Medical Association, and memberships in the American Orthopaedic Association, of which he was president in 1929, and the American Academy of Orthopaedic Surgeons

His widow, a sister, a daughter, a son and two grandchildren survive him.

NEW HAMPSHIRE MEDICAL SOCIETY

WOMAN'S AUXILIARY, AMERICAN MEDICAL ASSOCIATION

The eighteenth annual convention of the Woman's Auxiliary to the American Medical Association will be held in New York City, June 10-14, with headquarters in the Hotel Pennsylvania In view of the fact that the second edition of the World's Fair will accelerate advance hotel reservations, it is urged that reservations be made immediately through the Housing Bureau, which has been set up by the American Medical Association. Inquiries should be addressed to Dr Peter Irving, Room 1036, 233 Broadway, New York City

DEATH

BIELSCHOWSKY—ALFRED BIELSCHOWSKY, M.D., director of the Dartmouth Eye Institute, died in Brooklyn, New York, on January 5, at the age of sixty-eight.

Professor of ophthalmology and chief of the Eye Clinic at the University of Breslau, Germany, Dr Bielschowsky came to the Dartmouth Eye Institute as visiting ophthalmologist in 1934, and was appointed visiting lecturer in physiologic optics in 1935 Dr Bielschowsky had served as director of the Eye Institute since 1937 In addition to his work at Dartmouth, he had been an associate in ophthalmology at the Harvard Medical School since 1938

Dr Bielschowsky is survived by his widow, Frieda (Blume) Bielschowsky, and a daughter

MISCELLANY

VALUE AND LIMITATIONS OF THE TUBERCULIN TEST

The value of the tuberculin test as a means of finding cases of tuberculosis by mass testing has lately been questioned. At the last annual meeting of the National Tuberculosis Association a symposium on the tuberculin test and x ray was presented. One of the speakers (Long, E R. The Tuberculin Test Its value and its limitations. *Am Rev Tuberc* 40 607-620, 1939) summarized the values and limitations of the tuberculin test in a paper, from which the following abstract is derived

The queries and doubts that have arisen concerning the tuberculin test within the last two years have had a healthful effect on our anti tuberculosis campaign in forcing us to review our current procedures and test the validity of past beliefs This paper omits all discussion of the tuberculin test except as a means for finding cases of tuberculosis

In guinea pigs the test is practically infallible The success of the campaign for eradication of bovine tuberculosis, based, as it is, on the tuberculin test, is a strong empiric argument for the practical value of the test. The almost constant finding of tuberculous lesions in cattle slaughtered because of a positive tuberculin reaction, and the failure to find tuberculosis in the routine inspection of millions of cattle not reacting and killed for meat production, is tangible evidence for its specificity and adequacy In certain other animals, however, tuberculin allergy is far less conspicuous

Tuberculin sensitivity in man can never be studied with the same thoroughness as in guinea pigs or cattle. However, observations on children vaccinated with BCG have enabled us to study the results of artificial infection and its relation to tuberculin sensitivity and these studies indicate that after very mild infection an overwhelming majority of children become tuberculin positive.

We are here not concerned with the total number of tuberculin reactors that may be detected, but rather with the detection of significant tuberculosis by the use of the tuberculin reaction as a preliminary screen. ("Significant tuberculosis" or "a case of tuberculosis" in its public health sense, is restricted to infection with the tubercle bacillus which has proceeded to the point where it has produced symptoms recognized as those of clinical tuberculosis, or has brought about changes demonstrated by x-ray examination that are considered to indicate tuberculous disease) This definition places heavy responsibility on x-ray examination If the tuberculin test is used at all in case-finding, it is as a screen to obviate the necessity of the more expensive x-ray examination. (In young adult groups, one third or more of those tested with tuberculin may not react, and these need not be x-rayed.) It is believed by some that, on the basis of cost alone, saving x-ray examination of one third of the subjects would not counterbalance the cost of the tuberculin test.

What does the standard first and second dose method of tuberculin testing (fully defined by the author) detect and overlook? Of 610 cases of pulmonary tuberculosis diagnosed in the Henry Phipps Institute during five consecutive years, all but 1 reacted to tuberculin. Among the 609 reactors 94 per cent of the white and 96 per cent of the colored reacted to the first (minimal) dose (OT used in earlier PPD in later years). However, in other similar clinics and in hospitals attention is drawn occasionally to cases of unquestioned tuberculosis, even with positive sputum, in which the reaction is negative. Explanations for these exceptions are easily found: the fact remains that cases of anergy in typical hospital patients are probably few.

However clinic experience is not representative of the conditions of case finding as they occur in mass surveys. Some surveys deal with groups of high and others with low infection incidence. Evidence shows that the tuberculin test is an efficient preliminary case-finding measure in groups under relatively heavy exposure, as nurses in a hospital or sanatorium. For example among 400 nurses, 22 cases* of tuberculosis have occurred, all of which developed or already exhibited tuberculin sensitivity some months in advance of the onset of a recognized lesion, and no case has developed in the absence of tuberculin sensitivity. In groups under exceptional exposure the tuberculin test is an effective warning sign indicating the need of close and frequent observation.

Studies conducted by the United States Public Health Service and the Department of Health of Tennessee have shown that the tuberculin test is far from being the sharp indicator, once popularly supposed, of previous simple tuberculous infection. These studies disclosed a large amount of what appears to be healed primary tuberculosis in people not reacting to tuberculin. A supplementary survey conducted at Hagerstown, Maryland, however indicated that for case-finding purposes the tuberculin test is highly effective. In the 1000 subjects examined by both tuberculin test and x-ray, 13 cases of tuberculosis were discovered, all but 1 of which reacted to tuberculin; this case showed scarred apical disease of slight extent and had been apparently long arrested. The author believes that an accuracy of about 90 to 95 per cent may be expected of the tuberculin test as a means of selecting subjects for examination by x-ray but admits that a loss of 5 to 10 per cent is serious, but perhaps inevitable.

The attempt to divide all mankind into two groups infected and not infected, is futile and probably responsible for most of the present confusion. Two other groups must be recognized: those infected, not yet positive, but to be positive shortly thereafter and those infected and previously positive, but now negative. (A possible fifth group would include those who are infected and never develop a positive reaction.)

Allergy does not develop simultaneously with infection. There may be an interval of from two to three weeks between infection and a positive tuberculin reaction. In any large survey there may be a few cases recently infected and not tuberculin-positive. In some of these, x-ray lesions may develop.

The second group (previously positive, now negative) is more important and probably the greatest single cause for our present confusion. We have tended to overlook the fact that with the arrest and healing of tuberculous lesions allergy wanes and finally may disappear.

In a period, however when the mortality rate is dropping steadily and the morbidity rate is following in some proportionate relation, and when in addition an improved

control of tuberculosis is bringing about a steadily increasing isolation of patients with open lesions, it is only to be expected that reinfection the rule in the past, will become progressively less frequent. The infections that formerly constantly restored a waning allergy will be far less frequent in the future and we may look forward to the time when loss of allergy will be as common as its maintenance.

A study of 2490 positive reactors, all examined at the Henry Phipps Institute, showed that 276 or approximately 11 per cent, became negative, either transiently or for the balance of the period of observation. It was disclosed also that the stronger the original reaction the less frequently it reverted to negative and vice versa. Further the correlation with exposure was equally striking. In 58 per cent of the families in which no tuberculosis was present, the tuberculin reaction became negative in some member of the family while in families where there was continuously a member with sputum-positive tuberculosis, allergy disappeared in some member of the household in only 8 per cent of the families.

The fact that allergy tends to disappear where there is no exposure, and has more and more tendency to remain as exposure is presumably more frequent, suggests strongly that reinfection is responsible for the maintenance of the positive reaction. The epidemiological significance of this fact is obvious.

In the 276 cases in which the reaction became negative, no abnormality was detected in the film in 94 per cent and there were no cases of active reinfection type tuberculosis in the entire group. In 10 cases with what were read as calcified lesions, the reaction became negative.

Two cases are recorded in which tuberculin-negative children with calcified lesions became tuberculin-positive coincidentally with the development of fresh active tuberculosis.—Reprinted from *Tuberculosis Abstracts* March, 1940

NOTE

The seventh E. Starr Judd Lecture at the University of Minnesota was given on March 14 by Dr. Edward D. Churchill, John Homans Professor of Surgery, Harvard Medical School, and chief of the West Surgical Service, Massachusetts General Hospital. The subject was "Surgery of the Lungs."

CORRESPONDENCE

OBSTETRICS OF FORMER DAYS

To the Editor Just after the turn of the century a large number of immigrants of the laboring class came to this town. There was no birth control no race suicide. Among certain groups was a belief brought from the home country that if a woman did hard physical labor during her pregnancy and particularly during the first stage of labor the second stage would be easier and shorter. And perhaps they were right.

May I cite a case in point. Labor began while the woman was digging potatoes in a nearby field. When she could remain on her feet no longer she was carried to the house and placed in bed, just as she had been picked up. As usual, no physician had been engaged, but one was hastily summoned. He arrived barely in time to witness the birth. "Recovery was uneventful."

Similar incidents with minor variations could be cited

by the score, and all without casualties to mother or child.

What did it mean? It had led to natural selection of child-bearing women for generations in the home country—Mother Nature can do a pretty good job if she does not have too much assistance or interference.

Furthermore, it resulted in large families to those best able to produce them. I regret to add that the mothers of the next generations have not been so spontaneous or so productive, with seemingly far less resistance.

Those early immigrants called physicians only because they had been told that it was "the law" in this country. Only neighbors' wives attended the births "at home," but if a woman survived her first childbirth there was seldom any trouble in succeeding births. The death rate among primiparae was not known, as they were recorded only by the parish priest who attended the funeral. The living births were recorded at christenings, but the stillbirths were not reported at all, and the causes of death only when the priest made the diagnosis and recorded it if he saw fit.

As there are but a few of us left who were active among those people in that period I have felt that the history of that ten or fifteen years should be recorded.

Being a young man, recently out of college, I was able to learn and speak the necessary part of their language and so was much in demand. Incidentally, I was delighted to get ten dollars and satisfied with five dollars and often received only the twenty five cents for the birth return—perhaps it was all the service was worth in comparison with the time and care of the modern obstetric case.

FRANK T. WOODBURY, M.D.

21 Chestnut Street,
Wakefield, Massachusetts

NOTICES

REMOVAL

HAROLD N. MCKINNEY, M.D., announces the removal of his office to 149 Warren Street, Roxbury.

BOSTON DISPENSARY

A luncheon meeting of the clinical staff of the Boston Dispensary will be held on Friday, March 29, in the auditorium of the Joseph H. Pratt Diagnostic Hospital at 12 o'clock noon. Dr. Leonard J. Carmichael will give the second in a series of talks by different speakers on the past, present and future of the New England Medical Center and its component parts. Dr. Carmichael's subject will be "Tufts and the New England Medical Center."

All interested in the subject are cordially invited to attend.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, March 27, from 2 to 4 p.m. Drs. H. F. Newton and S. A. Levine will speak on "Dyspnea."

Physicians and students are cordially invited to attend.

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday evening, April 4, at 7:15 in the classroom of the nurses' residence. Dr. Laurence B. Ellis, the guest speaker, will talk on "Circulatory Failure." A question period will be led by Dr. Elsie W. Brown.

MASSACHUSETTS GENERAL HOSPITAL

A meeting of the Hospital Research Council will be held in the White Building Amphitheater of the Massachusetts General Hospital, on Tuesday, March 26, at 5:00 p.m.

PROGRAM

A New Method for Studying Bone Growth. Dr. T. H. Ingalls

The Treatment of Trigeminal Neuralgia with Vitamin B₁ (Thiamin). Drs. A. S. Rose and B. M. Jacobson.

Studies with Radioactive Arsenic

Demonstration of Radioactive-Tracer Counting Apparatus. Dr. A. F. Kip

Distribution of Arsenic between Blood and Viscera. Dr. F. T. Hunter

SUFFOLK DISTRICT MEDICAL SOCIETY

A meeting of the Suffolk District Medical Society will be held at the Boston Medical Library, 8 Fenway, on Wednesday, March 27, at 8:15 p.m.

PROGRAM

Scientific meeting

Acute Infectious Diarrhea. Dr. Roy F. Feemster

The Maintenance of Adequate Nutrition in Chronic Diarrhea. Dr. Maurice B. Strauss

Discussion by Drs. Chester M. Jones and Charles F. McKhann

NORFOLK DISTRICT MEDICAL SOCIETY

A regular meeting of the Norfolk District Medical Society will be held in the Hotel Somerset, Boston, on Tuesday evening, March 26, at 8:30. Tel. KEN 2700.

PROGRAM

Business

Diseases of the Colon from the Medical and Surgical Standpoints. Dr. Edward L. Young

Discussion to be opened by Drs. Charles W. McClure and John W. Spellman.

Collation.

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Mallory Institute of Pathology, Boston City Hospital, on Monday, March 25, at 8:15 p.m.

PROGRAM

Cor Triloculare in a Thirteen-Year Old Boy with Pulmonic Stenosis. Dr. O. J. Wollenman, Jr.

An Unusual Case of Dissecting Aneurysm. Dr. George Bartol

Anticoagulants and Sulfapyridine in the Treatment of Subacute Bacterial Endocarditis. Dr. C. N. Duncan.

Changes in the Cutaneous Circulation of Male Castrates and Eunuchoids. Dr. E. A. Edwards.

A Case of Temporal Arteritis. Dr. H. J. Jeghers.

Paroxysmal Precordial Pain in Mitral Stenosis. Dr. A. M. Burgess, Jr.

The Significance of Marked Left Deviation in the Electrocardiogram. Dr. J. M. Faulkner

Interested physicians and medical students are invited.

UNITED STATES MARINE HOSPITAL

The staff meeting of the United States Marine Hospital, Chelsea, will be held at "The Hut," on Friday afternoon.

arch 29 at 4-00. Dr Chester S. Keefer will speak, his topic being "Some Clinical Aspects of Acute and Chronic Bright's Disease."

MASSACHUSETTS TUBERCULOSIS LEAGUE

The annual meeting of the Massachusetts Tuberculosis League will be held on Thursday, March 28 at the Middlesex County Sanatorium, Trapelo Road, Waltham, Massachusetts.

PROGRAM

- 4.30 p.m. Personally conducted tours through Middlesex County Sanatorium.
- 5.15 p.m. Business session. Election of officers and directors.
- 6.30 p.m. Dinner
- 7.30 p.m. Prevention and Control of Tuberculosis in Massachusetts. Dr Frederick T. Lord.
- 7.50 p.m. The County Sanatorium and Its Work in Middlesex County. Drs. Sumner H. Remick and Henry D. Chadwick.

The dinner will be \$1.00 per person. Reservations should be sent to Massachusetts Tuberculosis League, 148 Little Building, Boston. Tel. HAN 5480.

WALTHAM MEDICAL MEETING

The regular monthly clinicopathological conference of the Metropolitan State Hospital will be held at the hospital on Wednesday evening, March 27 at 8-00. A case presenting features of neurological and medical interest will be presented by Drs. Richard C. Wadsworth and Emory Friedman. It will be discussed by Dr. Siegfried J. Thannhauser.

All interested physicians are cordially invited.

MASSACHUSETTS DEPARTMENT OF CIVIL SERVICE AND REGISTRATION

- School Physician (Male or Female) \$5 a Day Boston
- School Physician (Female) \$250 a Year Northampton
- School Physician (Male) \$1000 a Year Northampton

Director of State Civil Service, Ulysses J. Lupien has announced that competitive examinations are to be held on April 20 in order to find eligibles for appointment to the above positions.

The entrance requirement is as follows: applicants must be registered physicians under the State Board of Registration in Medicine. The last date for filing applications is Saturday April 6, at 12 o'clock noon.

INTERNATIONAL COLLEGE OF SURGEONS

The New England Activities Committee of the International College of Surgeons announces a program to be held at the Hospital of St. Raphael, New Haven, Connecticut, on Wednesday March 27

PROGRAM

- 9 a.m. to 12 m. A series of operations will be performed.
- 12 30 p.m. Luncheon.
- 2 p.m. to 4.30 p.m.
- Opening Address. Dr G. S. Foster
- Address of Welcome. Dr Joseph Lande.
- Appendicitis. Dr James A. Gettings.
- Spondylolisthesis. Dr Dennis O'Connor
- Partial Intestinal Obstructions. Dr Andrew McQueney
- Talk on Gastric Surgery. Dr Edward Kirschbaum.
- Gall Bladder Surgery. Dr A. J. Mendillo.
- On Head Injuries. Dr William German.
- Pathology. Dr Robert Nesbit.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY MARCH 24

MONDAY MARCH 25

- *8.15 p.m. New England Heart Association. Malvern Institute of Pathology Boston City Hospital.

TUESDAY MARCH 26

- *9-10 a.m. Diaphragmatic Hernias. Dr Joseph H. Marks. Joseph H. Pratt Diagnostic Hospital.
- 5 p.m. Hospital Research Council. Massachusetts General Hospital, White Building amphitheater.

WEDNESDAY MARCH 27

- 9-10 a.m. Hospital case presentation. Dr S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.
- 2-4 p.m. Dyspepsia. Drs. H. F. Newton and S. A. Levine. Peter Bent Brigham Hospital.
- 6.30 p.m. Tufts College Medical School Alumni Association. Hotel Somerset, Boston.

THURSDAY MARCH 28

- *9-10 a.m. The medical, social and preventive aspects of selected cases. Preceptors and medical students. Joseph H. Pratt Diagnostic Hospital.

FRIDAY MARCH 29

- *9-10 a.m. Some Observations on Pituitary Adenomas. Dr M. G. Soutman. Joseph H. Pratt Diagnostic Hospital.
- 12 m. Luncheon meeting of the clinical staff of the Boston Dispensary. Joseph H. Pratt Diagnostic Hospital.
- 8 p.m. New England Pathological Society. Peter Bent Brigham Hospital.

SATURDAY MARCH 30

- *9-10 a.m. Hospital case presentation. Dr Thannhauser. Joseph H. Pratt Diagnostic Hospital.

*Open to the medical profession.

- MARCH 25—Monthly clinical meeting and luncheon. Carney Hospital. Page 469 issue of March 14.
- MARCH 27—Clinicopathological conference of the Metropolitan State Hospital, Waltham. Notice above.
- MARCH 27—International College of Surgeons. Notice above.
- MARCH 28—Massachusetts Tuberculosis League. Notice above.
- MARCH 28—Staff meetings. United States Marine Hospital. Page 514.
- APRIL 4—Monthly clinical conference and meeting of the staff. New England Hospital for Women and Children. Page 514.
- APRIL 11—Pennsylvanian Association of Physicians. 8.30 p.m., Hotel Barlett, Philadelphia.
- APRIL 15-17—American Association for the Study of Gout. Page 203 issue of February 1.
- APRIL 15-19—New England Health Institute. Page 284, issue of February 15.
- APRIL 24—Massachusetts Dental Society. Page 365 issue of February 29.
- APRIL 24-25—Scientific Session. Academy of Physical Medicine. Hotel John Marshall, Richmond, Virginia.
- MAY 10-18—American Scientific Congress. Page 1043 issue of December 28.

MAY 13 — United States Pharmacopoeial Convention Page 202 issue of February 1
 JUNE 7-8 — American Heart Association Page 469 issue of March 14
 JUNE 7-9 — American Board of Obstetrics and Gynecology Page 1019, issue of June 15

BOOK REVIEWS

Transactions of the American Association of Genito-Urinary Surgeons Fifty-first annual meeting held at Absecon, New Jersey, May 2, 3 and 4, 1938 Vol. 31 405 pp St. Paul and Minneapolis The Bruce Publishing Co, 1938

This volume contains the proceedings of the annual meeting of the American Association of Genito-Urinary Surgeons and consists of twenty-nine papers by leading American urologists, together with the discussions of the papers. That the specialty of urology is constantly increasing its scope and connections with other branches of medicine is obvious from the variety of subjects dealt with, such as arterial hypertension occurring in unilateral kidney disease, transplantation of endocrine tissue, endometriosis of the bladder, adrenocortical syndromes and adrenal tumors, and the cure of lung metastasis from kidney carcinoma by lobectomy. Other papers deal with general principles of treatment, such as the treatment of cancer with the newer types of roentgen ray therapy, in addition there are the usual case reports of rare conditions, with reviews of the literature. All in all, this volume contains some excellent and important papers and evidences the progressiveness of American urology.

Pathogenic Microorganisms A practical manual for students, physicians and health officers William H. Park and Anna W. Williams. Eleventh edition. 1056 pp Philadelphia Lea & Febiger, 1939 \$8.00.

"Park and Williams" is now a classic text and from the beginning, when it was first published in 1899, has taken its place among the foremost treatises on bacteriology in any language. Well organized and thorough, it has always maintained that wise balance between theory and practical experience which characterized the mentality of its senior author. Dr. Park was one of the great American bacteriologists, his studies covered a wide range and he soundly and sagaciously correlated his specialty with medical practice and public health. He utilized, in the writing of this book, moreover, the accumulated experience of a distinguished group of collaborators at the New York City laboratories, among whom were Anna Williams, Charles Krumwiede and, in the present edition, Ralph Muckenfuss and other active and competent men and women. The book represents a complete and comprehensive treatise, it is a textbook and a reference book, a type which the reviewer favors over elementary and abbreviated texts, even for undergraduate medical students. It is one of the few books that include an excellent practical section on clinical protozoology and an adequate treatment of the yeasts and molds.

This edition is in every sense worthy of its predecessors and continues the fine tradition of Dr. Park whose recent death was an irreparable loss to science.

NUMBER 13

THE WARRENS OF NEW ENGLAND AND THEIR FRIENDS

HUGH STALKER, M.D.*

GROSSE POINTE, MICHIGAN

FORTY years ago Sir William Osler¹ said to the students of McGill "While medicine is to be your vocation, or calling, see to it that you have also an avocation — some intellectual pastime, which may serve to keep you in touch with the world of art, of science or of letters. Begin at once the cultivation of some interest other than

it is living it."² It is not examining faded writings on limp old paper, it is being with the writer as the letter is penned. We can slip back across the centuries and leave behind us this present materialistic world. Read in the spirit that it should be read, it is a book of memories that sweeps time away. That is only one of the joys of possession

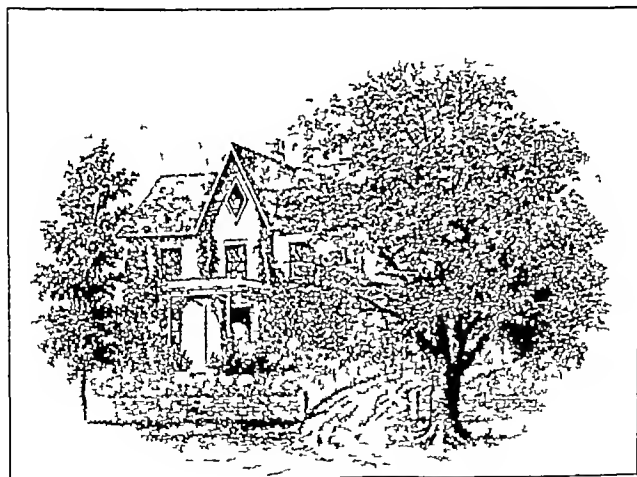

FIGURE 1 Warren House Roxbury

the purely professional. No matter what it is—but have an outside hobby.

Horace Walpole wrote "Nothing gives us so just an idea of an age as genuine letters: history waits for its last seal from them." To even the least imaginative there is a never-ending source of interest and curiosity in the contemplation of letters and documents written by great personages of the past and present. It is not reading history

There are many men in medicine

who never sing

But die with all their music in them.²⁷

Their names will not go down the avenues of the world with renown, but their simple lives have created in their small spheres better and happier days for those with whom they have come in contact. Letters from many of these are in my collection.

As I turn the pages of my book of memories, the year 1792 summons many a figure from my as

*Lecturer in physical diagnosis and cardiology, Wayne University College of Medicine, physician to Out Patient Department, Harper Hospital and Children's Hospital of Detroit, Michigan.

sociative memory I turn to old New England of post-Revolution days, where lived John Warren, the first of that line of doctors destined to go down in the history of American medicine as pioneers. His ancestor, John Warren, a fellow passenger with Governor Winthrop, sailed from England in the *Arbella*, arriving in Salem, Massachusetts, June 12, 1630.³ His grandson Joseph built the family home in Roxbury (Fig 1) where the first Dr John Warren was born.

JOHN WARREN (1753-1815)⁴⁻⁹

In his early years, indifferent to studying, John did not learn to read until he was ten years old. At the grammar school in Roxbury he applied himself more assiduously, and acquired sufficient learning to enable him to enter Harvard College at the age of fourteen, where he was entirely dependent on his own resources for maintenance. Little is known of his life at Cambridge except that he became a good student of the classics and acquired a facility in speaking the Latin language, which was essential to him later in communicating with many foreigners, both lay and professional, with whom the political issues of the times brought him in contact. His diligence and a tenacious memory enabled him to stand well in his classes during the whole college course. Even at this early age, he showed an interest in the study of anatomy and, by his efforts, an association of students was formed for the purpose of cultivating that study. He took the degree of Bachelor of Arts in 1771 and immediately began the study of medicine with his brother Joseph, some twelve years his senior.

Joseph Warren was the first surgeon in America to use ligatures instead of scarring wounds with the actual cautery, and was the first in Massachusetts to devote himself wholly to obstetrics. On April 19, 1775, having ridden hastily out to Dedham to ascertain that he was not urgently needed for an approaching confinement, Joseph mounted his horse and hurried to Concord, where he arrived in time to direct the pursuit and harassment of the British forces as they retreated to Charlestown. On June 14, he was commissioned a major general, but three days later, before his commission was made out, he took part as a volunteer at the battle of Bunker Hill and died from a wound in the head.

When John Warren was only twenty years of age, he settled in Salem and associated himself with Dr Edward Augustus Holyoke. This was the year of 1773, when it is said the tea was thrown overboard in Boston Harbor, and tradition has it that Warren took active part in the

demonstration. About this time he joined a militia regiment in Salem commanded by Colonel Pickering and became its surgeon. Two years later, with the Revolution in progress, he first learned of his brother Joseph's death and hurried to Bunker Hill, where, while seeking for the body, he received a thrust from the bayonet of a sentinel, the scar of which he bore throughout his life.

Dr Holyoke became one of his warmest friends. Aided by this influential patron and winning his own way by his personality and evident ability, he developed a practice which was second only to that of his sponsor. One might infer that he hoped eventually to inherit Dr Holyoke's practice, but the irony of fate intervened, for the old gentleman lived to see a century turn the corner.

Since Dr Warren's anatomical researches and studies aroused the curiosity of his friends, he gave a few private demonstrations for their instruction. In 1780, he successfully gave a course of dissections to his colleagues in the Military Hospital, which was situated in a pasture at the corner of Milton and Spring streets, in the rear of the present Massachusetts General Hospital. Here he was senior surgeon until the close of the war. At that time there existed a strong popular prejudice against dissections, therefore, these exercises were conducted with the greatest secrecy. In the following year, they were more openly accepted and the students of Harvard University were permitted to attend. It was during this year and for the first time in America that Dr Warren performed the operation for disarticulation of the shoulder joint, with complete success. Early in his professional life he performed one of the first abdominal sections recorded in this country. This operation consisted in the opening and evacuation of a dermoid cyst in the left hypochondrium. The patient recovered.

Through bequests previously made to Harvard University, there existed foundations for a professorship of anatomy and surgery. No person had as yet appeared whose achievements and knowledge in these fields were sufficiently great to entitle him to fill these important chairs. Dr Warren was an excellent lecturer, and according to Oliver Wendell Holmes, who was later the professor of anatomy, "The driest bone of the human body became in his hands the subject of animated and agreeable description." President Willard perceived how much the interests of the university might be promoted by the talents of Dr Warren, and in 1783 the first medical institution in New England was established, with Dr Warren in the chair of anatomy and surgery, a position which he continued to occupy for thirty years. To fill this

chair was a herculean task, for, when unable to go from Roxbury to Cambridge by ferry, he had to drive a circuitous road of twenty miles. With the time thus entailed, in addition to his three hours of lecturing, and his practice, he was more than busy. Strangely enough he did not receive his M.D., an honorary one, until 1786. At that time the exercises of the medical school were held in Holden Chapel (Fig. 2) in the College Yard, and continued there for more than a quarter of a century.

Dr. Warren was one of a group who founded the Massachusetts Medical Society, incorporated in

He was the father of seventeen children, the eldest of whom was John Collins Warren and the youngest Dr. Edward Warren, his biographer. We note from this biography that he was a man of ardent temperament and agreeable social qualities, and that his frankness, candor and hospitality were conspicuous traits.

For some years before his death he was subject to attacks of angina pectoris, and in 1811 he suffered a slight paralysis of the right side, which never entirely disappeared. Four years later, when only sixty-two years of age, this patriotic and public spirited physician died of an acute illness,

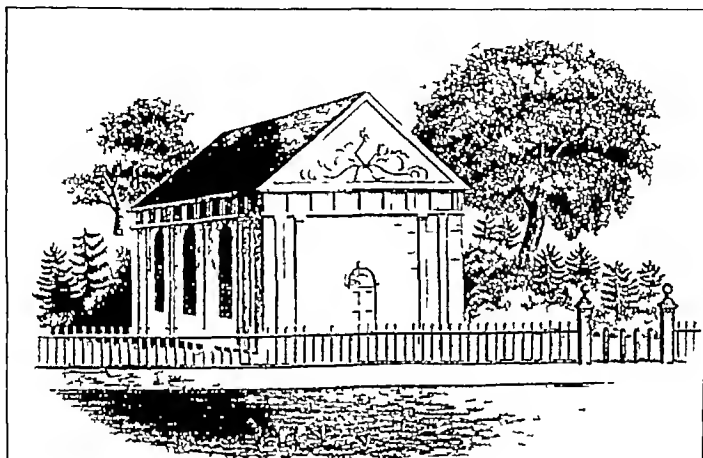

FIGURE 2 Holden Chapel Cambridge

1781, the first body in Massachusetts to establish a standard and issue a license to practice, a requisite which has come down to the present day. Two years later he delivered the first Fourth of July oration from the balcony of the State House in Boston, probably the oldest public building in America. The next year, with several other doctors, he established a smallpox hospital at Point Shirley and in 1792 inoculated more than fifteen hundred persons. He recognized six years later that yellow fever was non-contagious. In 1810, by his efforts and those of his colleagues, the medical branch of the university was moved to Boston. His most notable contribution to literature was a paper, appearing in 1813, entitled "A View of the Mercurial Practice in Febrile Diseases," in which he referred to the treatment of many of the prevailing diseases of that period, such as measles, "throat distemper," consumption, dysentery, spotted fever and spinal meningitis.

having, faithfully continued to visit his patients up to within a few days of the end. He was remembered as a presence to be felt and known."

JOHN COLLINS WARREN (1778-1856)⁴ 6 8, 10-12

It would be well today if all members of the medical profession and also those engaged in business would read the beautiful and noble "Dedication of *Letters to a Young Physician*" addressed to John Collins Warren by his friend James Jackson, than which there is "nothing finer in the medical literature of our time."

On the death of John Warren his eldest son became Hersey Professor of Anatomy and Surgery at Harvard University. While it may be questioned whether his natural abilities as a teacher were as great as those of his father, he was undoubtedly a more highly educated man, having had the advantage of foreign study, and having been familiar with the teachings of the immediate

pupils of the celebrated John Hunter of Guy's Hospital, London. Shortly before leaving Paris after a sojourn of several months, he received an invitation, or order, from Napoleon to join the French army which was then organizing in Italy. His father, however, was anxious for his return and, obedient to his filial duty, Warren turned his back on his desires and came home.

As early as 1799, realizing the value of anatomical specimens as an aid to medical teaching, he brought with him from Europe a few models and preparations. These formed a nucleus, which he gradually increased during the first half of the

preceding the first in Great Britain by one year. Dr. Warren was one of the first surgeons in America to operate for strangulated hernia but met with great opposition, both from the friends of the patients and from the medical men. He was prominent also in the establishment of the American Medical Association, and in 1849 became its third president.

On October 16, 1846, occurs this entry in his journal: "I did an interesting operation this morning while the patient was under the influence of Doctor Morton's preparation to prevent pain. The substance employed was sulphuric ether." This

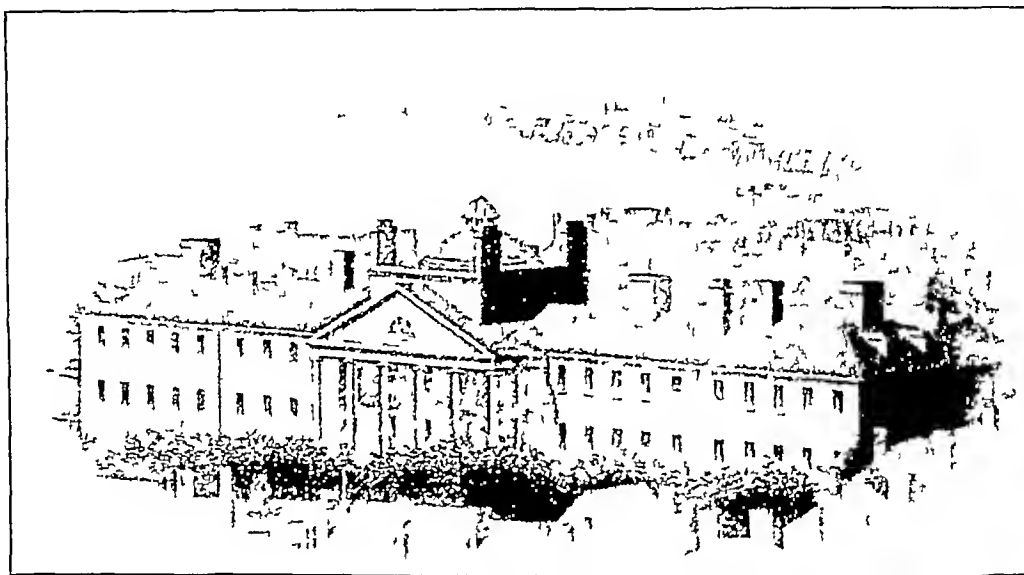

FIGURE 3 *Massachusetts General Hospital*

last century, until his collection became justly celebrated and was visited by physicians and students from far and near. Later this collection was given to the Harvard Medical School, where it was placed in the Warren Anatomical Museum. Body-snatching flourished at this time, but to what extent the corpses were procured by the connivance of officials, we do not know. Today an enlightened civilization recognizes the necessity of providing cadavers. Anticipating this by several years, Dr. Warren bequeathed his own body to the school, and his skeleton was prepared and placed in the museum, where it may be seen today.

In 1823 he purchased three acres of land, and with the aid of public subscription secured funds for the erection of Bunker Hill Monument, the cornerstone of which was laid by Lafayette and dedicated by the notable oration of Daniel Webster. Two years later, Dr. Warren was one of a committee appointed to draw up an act on dissection, and on February 28, 1831, the first anatomical law was passed in the United States,

laconic entry is the only reference made to the most important and dramatic event in the history of medicine in America. The operation was performed in the amphitheater of the Massachusetts General Hospital, then in the old Bulfinch Building (Fig. 3), the ether being administered by William T. G. Morton (1819-1868), an American dental surgeon.

After Dr. Warren had resigned from the Harvard Medical School and the Massachusetts General Hospital, he was able to spend more time in his paleontological work. Gradually this amazing life drew toward its close, and on May 4, 1856, at the age of seventy-eight, the end came after a brief and painless illness. Oliver Wendell Holmes said: "Whatever place he acquired or maintained no man can say that he did not earn it and keep it by his own fair labor."

JONATHAN MASON WARREN (1811-1867)^{4 6 8 13 14}

The third generation was represented by the second son of John Collins Warren, who was born in the house at 2 Park Street, Boston. In

1820 he entered the Boston Latin School, the old est school in the United States (founded in 1632), and remaining there through the full term graduated with his class in 1825. After studying two years with a private tutor, he was admitted to the sophomore class of Harvard College, but at the end of three months, because of ill health, he was obliged to leave. He went to Cuba to recuperate, and in the spring of 1828 returned to begin his medical studies under the tutelage of his father, Mason, as he was called, retained his associations with the Harvard class of 1830, receiving the degree of Master of Arts in 1844. Five years later he became a member of the Phi Beta Kappa Society. It was the custom of the time, dating from the period when the medical school was still at Cambridge, for the students to serve an apprenticeship, and the Warren home was the general gathering place. Near the front entrance a room with a sanded floor was provided for the purpose of study, and another was given over to the students for their meals. Gradually this practice yielded to the more modern system. In the fall of 1830 Dr. Warren entered his name as a student at the medical school on Mason Street from which he graduated in 1832 at the age of twenty-one.

In March of the same year, Dr. Warren sailed from Boston for Europe on the ship *Dover* which stopped en route at Charleston, South Carolina, and at the end of May he reached Liverpool where he found an epidemic of cholera raging. After visiting the clinics of Astley Cooper and Charles Bell in London, and Syme and Liston in Edinburgh, he arrived in Paris in the fall. In the band of American students who gathered there between the years of 1820 and 1840 were enrolled the majority of the most celebrated teachers and leaders of American medicine during the middle of the nineteenth century, notable among whom were Jackson, Bowditch, Holmes, Shattuck, and many more whose names on earth are dark. This group was known afterwards as the pupils of Louis. Following two winters of study in Paris, Dr. Warren visited Dublin in the spring of 1834, where Kennedy was master of the lying-in hospital and Macartney was presiding over his interesting museum at Trinity College. The winter of 1834-1835 was spent in Paris, where he watched Dieffenbach, on a visit from Vienna, perform his rhinoplastic operations. He also learned from Roux his method of operating for cleft palate, an ailment with which his own name was destined later to be intimately associated. In June, 1835, he returned home and prepared to begin his professional career.

When his father left for a visit to Europe in 1837, he entrusted a large practice to his son's care. Mason was eminently successful and became prominent, both as a medical and later as a surgical practitioner, for he was well qualified for these duties by a sound education, backed by good judgment and enhanced by a magnetic personality.

On April 30, 1839, he married Anna Caspar, daughter of Benjamin William Crowninshield, congressman and at one time Secretary of the Navy under Madison.

In 1843 he published his first article on staphylorrhaphy, an operation in which he was the pioneer in this country, the method which he devised being substantially that which is employed today. A full account of this operation is given in his book, *Surgical Observations and Cases* published in 1867, in which he refers to one hundred operations performed by him for fissure of the soft and hard palate. He also performed the first operation in America for the restoration of the human nose.

In February, 1846, Dr. Warren was elected one of the visiting surgeons of the Massachusetts General Hospital, and on October 16 of the same year assisted his father in the operation which was destined to be known as the first public demonstration of surgical anesthesia. A few weeks later he substituted in place of Morton's apparatus the cone-shaped sponge that was used to administer ether at the hospital for the next twenty years.

Though never robust, Mason Warren seems to have permanently suffered from the shock of a train accident which occurred on his return from a meeting of the American Medical Association in New York. This sent him to Europe twice in the following years. In 1864 he delivered the annual address before the Massachusetts Medical Society on "Recent Progress in Surgery," which summarizes well the status of surgery immediately preceding the antiseptic era.

He was senior surgeon of the Massachusetts General Hospital for the several years preceding his death from cancer of the gastrointestinal tract, he died in the very house in which he was born fifty-six years before. He was survived by his wife, four daughters and a son, John Collins Warren. Dr. Warren was a man of sensitive mind and distinguished bearing. He combined a cheerful disposition with an understanding which made him popular with patients and friends alike.

JOHN COLLINS WARREN II (1842-1927)* 18-19

The two discoveries—anesthesia and antiseptics—that have had the most profound influence on medical science came within the lifetime of John

Collins Warren, the son of Jonathan Mason Warren. The discovery of ether anesthesia was made when he was but a child, yet the controversies which followed it extended into the period of his early medical career, and he remained to the last a supporter of the claims of Dr W T G Morton as its real discoverer. In 1869 Dr Warren visited Lister in Glasgow, and made a study of his methods of employing antiseptics in surgical operations. On his return to Boston he assumed an active part in the introduction of these methods at the Massachusetts General Hospital.

The microscopic study of pathologic material derived from operations was at this time in its infancy. Dr Warren was one of the first in this country to develop the practical application of this study, not only for the benefit of the individual patient but also for the investigation of surgical disease. During the Civil War, while still a student, he served as a medical cadet in the Union forces, and there developed an interest in and a knowledge of surgical infections, which years later led to the writing of *Surgical Pathology and Therapeutics*, his most notable literary accomplishment.

Loyalty and devotion to the Massachusetts General Hospital and to its traditions were bred in the very fiber of Dr Warren's being. Through all the stages of promotion from house pupil to senior surgeon, he gave to the hospital the best he had. As a surgeon he was courageous, resourceful and thorough, he was admired and loved alike by his patients and his assistants. His Sunday ward visits when he was a senior surgeon were never to be forgotten. Each case on the wards was reviewed and discussed, all with a nice formality and kindly courtesy that was an inspiration to the group of assistants and younger colleagues who made it a point to attend these occasions. His deepest interest was in the surgery of tumors, and it was in this subject that he made his greatest contribution to the advancement of surgical knowledge and practice, notably in cancer of the breast. In 1896 he was chosen president of the American Surgical Association. He held the post of Moseley Professor of Surgery in the Harvard Medical School from 1899 to 1907, when he became emeritus.

A clear, systematic thinker, widely read in surgical literature and endowed with a happy faculty for apt illustration by anecdote or example, Dr Warren made an admirable teacher of surgery. His influence was felt by many generations of students in the medical school and the hospital. The time and attention he gave to the preparation of his lectures and clinics served as a standard to

his younger assistants, and the readiness with which he sacrificed his personal comfort or pleasure to this purpose was an inspiration to them, and a fair indication of the great respect in which he held his duties and privileges as an instructor of medical students.

On his retirement from active hospital service in 1905, Dr Warren gave up his private practice and devoted himself unremittingly to the promotion of the many interests with which his varied life had brought him in contact. Chief among these was the Harvard Medical School. When it became necessary to move the school from the inadequate buildings on Boylston Street, it was to him and to Dr Henry P Bowditch that there came the vision, the faith and the ability to conceive the magnificent project for the present buildings on Longwood Avenue, and to secure the great fund needed for their construction and endowment. We may rejoice that Dr Warren at least lived to see this vision materialize, as one after another of the hospitals and laboratories necessary to the completion of this great medical center came to occupy their places in accordance with the original plan. Even the dormitory for medical students, a gift from Harold Vanderbilt, which Dr Warren was the first to advocate, but which at that time seemed so remote as to be beyond all expectation, came into being and was actually opened before his death.

In 1899 a sum of money was left by the will of Caroline Brewer Croft for the investigation of the cure of cancer, and Dr Warren was named a trustee of the fund. This bequest led to the organization of the Cancer Commission of Harvard University, of which he was chairman for many years. Under his guidance, and chiefly because of his interest in this subject and of his happy faculty for securing and sustaining the interest of others, the commission added immeasurably to its resources and extended its activities. The early funds for the construction of the Collis P Huntington Memorial Hospital for Cancer Research were obtained almost entirely by Dr Warren's efforts. The dedication in 1922, by the President and Fellows of Harvard College, of the adjoining laboratory building, to be known as the J Collins Warren Laboratory, was held by him to be the supreme honor of the many accorded to him in his professional career.

Dr Warren had an almost boyish simplicity and directness, and a sense of humor which contributed in no small degree to the facility with which he established himself in the hearts of those about him. Neither his honors nor his accomplishments but rather his character and personality left that indelible impression on all with whom he came in

contact. His sincerity, his unfailing courtesy,—reminiscent of a generation earlier than his own—his indefatigable industry and his loyalty were the striking qualities which endeared him to his patients, his students and his colleagues.

Born of a family whose name for more than a century had meant not only eminence in the medical profession but also the highest ideals of service to the community, carrying on this trust successfully with its manifold duties and its obligations and laying down the burden only after having seen the accomplishment of his most cherished ambitions—this is the epitome of the life of John Collins Warren II. In his sixty-one years of professional life, he sought and found opportunity to maintain the enviable heritage of the traditions of his illustrious forbears and to add materially to their brilliant record.

JOHN WARREN (1874–1928)¹⁻¹

With the death of Dr. John Warren, the elder son of John Collins Warren II, there ceased to be, for the first time in one hundred and sixty-four years, a Warren to minister to the medical necessities of New England. Beginning with the entrance into practice of Dr. Joseph Warren in 1784, members of this stock, for all but twelve years in direct lineage, had practiced and taught medicine in Boston. John's brother, a year younger, was christened Joseph, so that, in this fifth generation, the two brothers held the same simple names as the brothers of Revolutionary fame.

From his mother John Warren inherited his fair complexion and his great size. As a boy he grew so rapidly that at school and even at college he was unable to enter into athletics with any degree of merit and skill. His height made him a conspicuous figure and induced a certain amount of shyness and reserve. Beneath these traits and his dignified manner was a truly gentle and lovable nature which few, perhaps, were given the opportunity to appreciate. He prepared for college at Noble's School and entered Harvard with the class of 1896. After graduating he attended the medical school, as it was almost inevitable that he with such ancestors, should follow the medical profession in one of its many branches. The practice of surgery held no attraction for him, so that after his graduation he became an assistant in the Department of Anatomy. He devoted himself enthusiastically to teachings, and to the improvement of its methods. When appointed associate professor in 1915, he began the formation of a teaching anatomical museum, available to the students at all times. This contains a series of frozen sections of the body and many illustrative dissec-

tions, each accompanied by a carefully labeled photograph. He raised a memorial fund for Thomas Dwight, a kinsman of the Warren family and former professor of anatomy, which consisted of a collection of anatomical specimens invaluable to the student.

From 1911 until his death he was the university marshal and was in charge at all Commencements, where he made a very imposing figure. During the war, he attended the first Plattsburg training camp and at once enrolled as a medical reserve officer. He was interested in collecting books having to do with the history of anatomy, and it seemed assured that he like Osler and many others, would experience the lasting joy and interest of the bibliophile. It was not to be, for he died at the age of fifty-four just one year after his father had passed on. His collection, together with the entire medical library of the Warren family, is now at the Harvard Medical School. His interests, other than his work, were few: his tastes simple—long country walks, or as some of us may remember, daily walks from his home to the school with coat-tails flapping and cane swinging. The latter, and his manner of clasping his belt with his thumb and rocking up and down on his toes while lecturing, his many idiosyncrasies of speech and his individual choice of words, will long be remembered by his students, and will keep him vividly before us as a true and scholarly gentleman, a masterly teacher.

HENRY INGERSOLL BOWDITCH (1808–1892)²⁻²²

Another name famed in the annals of medicine is that of Bowditch. Henry the third son of Nathaniel Bowditch, the celebrated mathematician and navigator, was born in Salem, Massachusetts, in 1808. His boyhood was passed in the house still standing on Essex Street next to the Old Witch House.

When he attended the Harvard Medical School his chief instructor was James Jackson, a noble, wise and conscientious physician and an excellent teacher who in those days stood at the head of his profession in Boston. Later Dr. Bowditch was under his guidance as an intern at the Massachusetts General Hospital. In the spring of 1832, through the kindness of a generous father, he was enabled to go abroad to pursue his medical studies. In Paris at La Pitié together with James Jackson, Jr., who died two years later, Oliver Wendell Holmes and Mason Warren he "walked the wards" with Louis. He met and was entertained by Magendie, the physiologist and later in England by Sir Astley Cooper, the surgeon. It was while in London that he met the young Olivia Yardley who later became his wife.

On his return, Dr Bowditch found a Boston seething under the tremendous denunciations of William Lloyd Garrison Bowditch became an abolitionist, and aided in the initial steps which led to the final passage of the law of the Massachusetts legislature forbidding the use of the

plans were discussed for the prevention of yellow fever, made possible by the \$5,000,000 grant from Congress Comparing the board's problems with present-day public ones, we note the similarity in human nature Dr Bowditch, in a letter to his son, tells of the many demands on the money

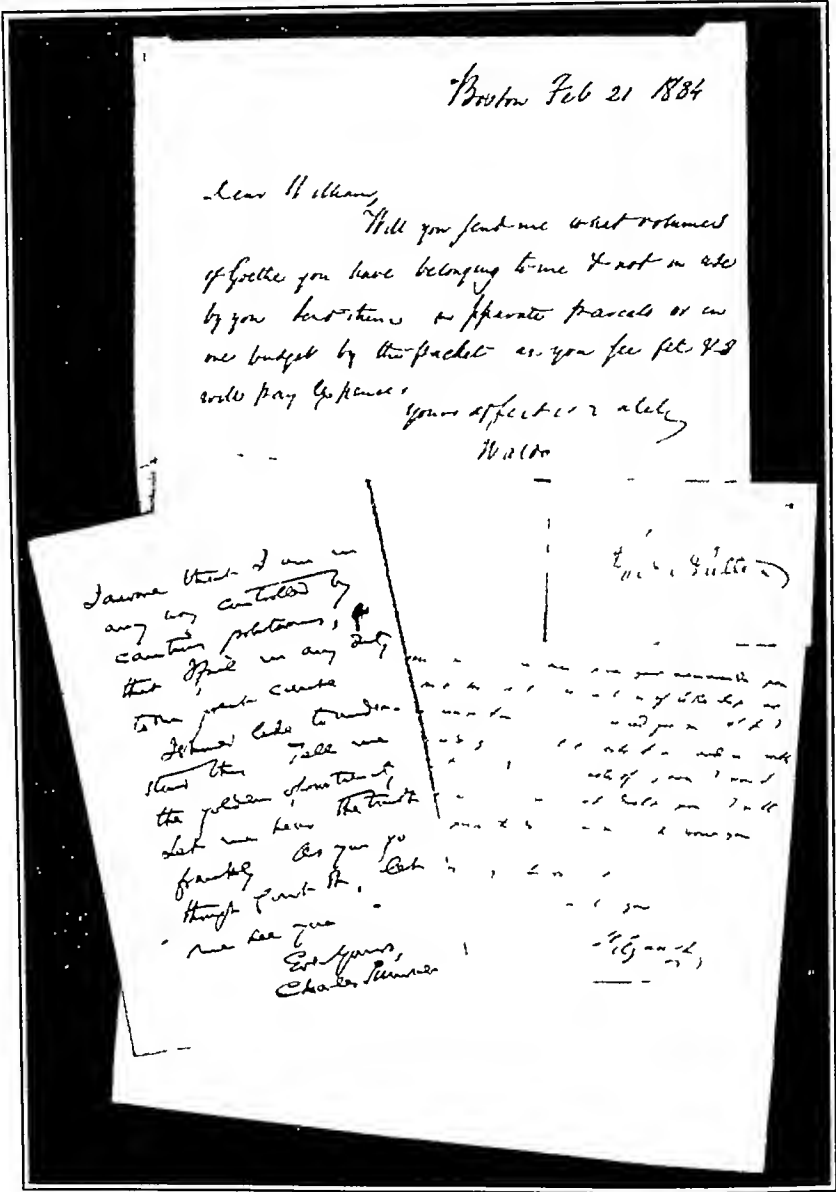

FIGURE 4 Letters of Friends of Henry Ingersoll Bowditch

Harvard Medical School

state and town jails for the detention of runaway slaves Because of his activities along this line and others, he numbered among his friends James Russell Lowell, John Greenleaf Whittier, Ralph Waldo Emerson, Louis Agassiz and Charles Sumner (Fig 4)

In 1879 he spent a few days in Washington at the National Board of Health meetings, where

We would not let every two-penny township have its quota, as it is called, of the money put in our hands. Some of these men demanded that we should build them systems of sewers, etc, and because we would do no such thing, they have berated us The national board, by aiding the local board and spending freely the nation's money, has prevented the spread of the fatal disease in the Mississippi Valley, and we shall probably be able to return to Congress more than half the money allotted to us

Because of an ankylosed finger, the result of an infection, Dr Bowditch was forced out of the surgical field, so he resolved to specialize in diseases of the lungs and heart. Though opening the chest wall to remove accumulation of fluid had been done surgically from the time of Hippocrates, it was not until 1850 that Dr Bowditch introduced aspiration or paracentesis by means of a small tube and a suction pump.

Dr Bowditch lived a very active life, wrote many medical papers, carried on a large practice, was an ardent worker for the advancement of medicine, took part in medical meetings and was a voluminous correspondent until he died in 1892. He believed that a physician should be, so far as possible, a man of general culture and should not confine his knowledge to his profession alone lest he become a man of one idea and of narrow vision. His philosophical views to his son Vincent may well be taken to heart.

The chief advantage of your going abroad is to see the methods of medical men on the other side of the water to find wherein they excel or are inferior to us. While medicine is your chief aim, remember that I want you to see and hear all that you can of art and music. I often think I have done more good to some weary patients by sitting down and telling them of a delightful European experience than by all the drugs I have ever poured down their throats.

VINCENT YARDLEY BOWDITCH (1852-1929)²² 23 24

Dr Bowditch's son Vincent, a very good friend of mine, was born in Weston, Massachusetts. He graduated from the old Brimmer School in Boston and prepared for college at a private institution before entering Harvard, from which he graduated in 1875. He ranked high in his classes but found time to enjoy athletics. He was always popular with fellow students, and became chief marshal on Class Day. After three years at Harvard Medical School, and a year's service as a medical house officer at the Massachusetts General Hospital, he received his degree of Doctor of Medicine in 1879.

The ensuing two years were devoted to attending lectures and clinics in various European medical centers, but Dr Bowditch did not lose sight of his father's admonition, for he was a frequent visitor at the operas, theaters and art galleries.

In 1889, interested in the proper treatment of pulmonary tuberculosis, he went to Goerbersdorf, Silesia, and visited the sanatorium of Dr Herman Brehmer and afterward that of Dr Dettweiler (Brehmer's pupil) at Falkenstein, near Frankfurt, Germany. There was a difference of opinion as regards fresh air, rest and altitude in treating this disease. Here in America, at that time, it was be-

lieved that but one course was open—to send a patient "out West." Dr Bowditch believed that the same results might be accomplished nearer home and, filled with enthusiasm, he established in 1891 the Sharon Sanatorium at Sharon, Massachusetts, with accommodations for nine women. Later he was instrumental in establishing Rutland Sanatorium at Rutland, Massachusetts,—the first state tuberculosis sanatorium in the United States,—and he held the position of attending physician for eight years from the opening to October, 1898. In both these institutions, his work served chiefly to prove that there was much benefit in being treated by proper methods of living. The excellent results attendant on his method attest the great value of his work there.

Dr Vin, as his young friends called him, was always abreast of the times, establishing a preventorium for children at Sharon and an occupational department at Rutland for those capable of working. He was a great friend of Dr Edward Livingston Trudeau, who was a pioneer in tuberculosis, and who opened Saranac in the Adirondacks seven years before Dr Bowditch opened Sharon.

Dr Bowditch was president of the National Tuberculosis Association (1908-1919) and first president of the Massachusetts Tuberculosis League, founded in 1914. He died in Boston, at his home, December 20, 1929, of tuberculosis—the enemy to which he had given his life that he might overcome it in others.

His intelligence, his persistence in conquering obstacles, his high ideals, together with his delightfully uncomplicated and sympathetic nature, shared in contributing to the vigor and attractiveness of his personality. He was a frequent visitor at the Tavern Club, he was an ardent follower of the Boston Symphony Orchestra and, when his duties did not interfere, one could usually find him in his regular seat at the Friday afternoon concerts, he loved to sing and was well versed in the German lieder. The theater always intrigued him, and he kept abreast of the good current literature. In short he was a gentleman of the old school and a distinguished figure in the intellectual life of Boston.

HENRY PICKERING BOWDITCH (1840-1911)²⁴

This nephew of Henry Ingersoll Bowditch was born in Boston and graduated from Harvard College in 1861. He was a major of the Fifth Massachusetts Cavalry, a Negro regiment, during the Civil War. Following his service he resumed his studies and graduated in 1863 from the medical school. He then spent three years studying with Claude Bernard in Paris and Carl Ludwig in Leipzig, where he wrote his paper describing the all-

or-none law of the heart muscle. On his return to this country in 1871, he served as assistant professor of the newly created Department of Physiology at Harvard, establishing for the first time in the United States a physiological laboratory for students. Five years later he was made full professor.

At this time the method of instruction in the Harvard Medical School underwent a radical change, the most important feature of which was the adoption of the so-called "course." Up to that time the students of the school were not classified according to the time spent in study, but each one was expected to select from the instruction offered such subjects as seemed to him best adapted to his needs. Thereafter the students were divided into classes, and the subjects pertaining to an education in medicine were classified as first-, second-, third- and fourth-year studies, an examination at the end of the year testing the student's fitness to advance from one class to the next. Under this arrangement physiology was classified as a first-year study, however, in recognition of its importance as an experimental science, it was accorded a position as an independent department of the school and a fairly commodious laboratory was provided by raising the roof of the North Grove Street building.

In 1899 Prof Bowditch withdrew from the greater part of his work, and in 1906 he resigned from the George Higginson Professorship of Physiology. To him belongs the credit of first appreciating that the whole system of laboratory accommodations must be organized on a greater scale than had ever before been attempted, and in association with Dr John Collins Warren II he devised a scheme along the broad lines on which the plans of the new school have been worked out. He proposed a group of buildings arranged somewhat on the plan of the modern German medical school, the various departments being housed in separate institutes. He acted on a committee with Dr Warren, John D Rockefeller, Jr, and the president of the University, Charles W Eliot. Through the generosity of J P Morgan and John D Rockefeller, Jr, a fund was started, and in 1903 land was broken for the erection of the present buildings of the Harvard Medical School.

Prof Bowditch's last years were saddened by the gradual limitation of his vigor and activity through the advance of paralysis agitans. But throughout the gradual decline, he accepted his fate with cheerfulness and with gentle consideration of those about him. He died at his home in Boston on March 13, 1911, and was survived by his widow, the former Selma Knauth, whom he had met in

Leipzig, and a family of sons and daughters. One of the last times that he appeared in public was in Sanders Theater at the ceremony for the dedication of the new medical school buildings. The occasion was a memorable one, and Prof Bowditch's impressive figure, clad in the scarlet robes of the Edinburgh doctorate, and seated at the front of the platform side by side with Dr Warren, made a fitting center for the striking scene.

Prof Bowditch cultivated his friendships in many happy ways, both at his home in Boston and at his summer camp in the Adirondacks. He possessed unfailing courtesy, fairness and good will, warmed by a delightful sense of humor. His ingenuity and effectiveness were manifest not only in physiological research but in matters of affairs. He possessed a rare combination of sober judgment and vigorous will—the qualities of a natural leader.

JAMES JACKSON (1777–1867)^{27-29 30 31 32}

The turning point in clinical medicine from idealism, speculation and theory to accurate and close observation came with the Hunters and Heberden, coincident with the American Revolution, so that when James Jackson received the degree of Bachelor of Physics from Harvard in 1802, the time was ripe for the development of modern medicine.

James Jackson's ancestors migrated to this country in the 1630's and were among the first to settle in Cambridge, a name chosen in honor of the ancient seat of learning in England, the intellectual parent of Harvard College. Thirty-eight Jacksons, all enlisting from the town of Newton, a suburb of Boston, fought in the armies of the Revolution, and fourteen of the descendants were in active service in the Union army during the Civil War of 1861.

Dr Jackson's father, Jonathan, was born in Boston, and moved to Newburyport, a coast town north of Boston, after the death of his parents. He was a public-spirited individual and in 1775 was chosen a representative to the first Continental Congress. Later he was appointed United States marshal for the District of Massachusetts, then including Maine, and superintended the taking of the first census (1790) of that part of New England. For the five years preceding his death in 1810, Jonathan Jackson served as treasurer of Massachusetts and for three years as treasurer of Harvard College.

James Jackson was born in Newburyport in 1777. Later on moving to Boston he attended the Boston Latin School. His medical education commenced in his senior year at Harvard College when

he attended lectures given by the medical professors. Then followed two years of apprenticeship with Dr Edward Augustus Holyoke, of Salem, a remarkably able practitioner, during which time Jackson took the regular course of medical school lectures. In October, 1799, he went to London where he studied with Astley Cooper, Woodville, famous in connection with smallpox vaccination, and other influential men. He renewed his acquaintance with John Collins Warren

library in Boston, and was thought by many to be the outstanding medical man of his day in America.

Dr Jackson, a man of wide culture and remarkable mind was one of the founders of the Massachusetts General Hospital, and for many years he occupied the chair of theory and practice of physic in Harvard. He was one of the first physicians in America to practice vaccination, and made important observations on the nature of typhoid

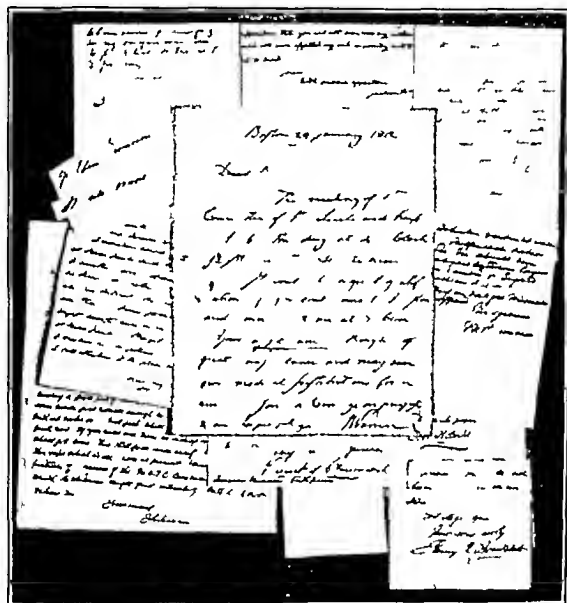

FIGURE 5 Letters of Those Mentioned in This Article
Reproduction from a collection to be given to the library of the
Harvard Medical School

which ripened into an intimate friendship lasting throughout the latter's life. Their names are united with the development of many progressive accomplishments.

For an American of that day Jackson's medical training was excellent and furnished him with sound background to become a professor. As was the custom of the time, he started practice one and a half years before he received his degree. With John Collins Warren, he was largely responsible in 1803 for furthering the organization of the Massachusetts Medical Society, and in 1808 for preparing its pharmacopoeia. He was also associated with the earliest attempts to form a medical

fever. In 1816 he published a syllabus of his lectures in practice. After his wife's death, he was joined by his son Francis and his family, with whom he lived until his death at ninety years of age. The last year of his life he was an invalid, but until then his mind remained unimpaired. *The Memoirs* of his son and *Letters to a Young Physician* are his literary offerings other than his medical writings.

Oliver Wendell Holmes wrote

James Jackson a man of serene and lean intelligence not ever book-fed truthful to the centre a candid listener to all opinions, a man who forgot himself in his care for others and his love for his profession by com-

mon consent recognized as a model of the wise and good physician I have seen many noted British, French, and American practitioners, but I never saw the man so altogether admirable at the bedside of the sick as Doctor James Jackson. His smile was itself a remedy better than the potable gold and the dissolved pearls that comforted the praecordia of medieval monarchs. To visit with him was a medical education.

JAMES JACKSON, JR (1810-1834)^{28-31 35 36}

James Jackson, Jr, whom Osler called the young Marcellus* among the physicians of this country, —“the young Marcellus, young, but great and good,”—was the fifth child of James and Elizabeth Cabot Jackson.

From the earliest the boy was always cheerful and happy, never long depressed by trouble of any kind. Though industrious and given to systematic habits of study as a youth, he did not achieve any outstanding distinction for scholarship during his college career. Instead of striving for class honors, he devoted himself to a broader reading, and stored his mind with the valuable facts thus acquired. He graduated from Harvard in 1828 at the age of eighteen and then studied medicine under his father and attended lectures at the medical school, making free use of the clinical material at the Massachusetts General Hospital.

In 1831, when just past twenty-one years of age, he went to Europe to continue his studies in the hospitals of Paris, and there for two years under the personal guidance of the great master, Louis, —who had from the first become warmly interested in him and who stood to him ever after as “my second father and God knows that is a name I of all men cannot use lightly,”—he observed and reported his observations.

He chose particularly to follow Louis at La Pitié instead of Chomel at Hôtel Dieu, because the former had not more than fifteen students and visited the wards in the daylight, thus giving him greater opportunity to listen with the stethoscope to more patients, whereas the latter was often surrounded by two or three hundred pupils and made rounds by candlelight one and a half hours before clear day. Jackson felt with Cervantes that “Knowledge of the disease is the beginning of healing.”

Although but twenty-three years old and not yet possessed of his medical degree, James had won a reputation which an experienced physician might have envied. A brilliant career seemed assured to him, and a social life enriched by the affection of a host of friends. He reached home at the end of the summer of 1833, and received

the degree of Doctor of Medicine from Harvard in February, 1834. He was then prepared to engage in practice and, as was the custom in those days, sent an advertisement to the public papers, which appeared on March 5. On the same day he fell ill with a dysentery, which proved fatal about three weeks later.

The blow to the father was a terrible one. But soon he began to collect material for a memoir to his son. In this book are presented his letters to his father, written during the winter of 1831-1832, which are almost wholly given up to enthusiastic descriptions of auscultation and percussion phenomena, histories of cases and arguments of diagnosis, interspersed here and there with illuminating remarks concerning his teachers, his surroundings and himself. From this correspondence, it is clear that the son and father exchanged *cliniques* in their communications as well as personal and domestic matters. There are also included a considerable number of cases of cholera, valuable contributions to the pathology of that disease which James had collected in Paris in the spring of 1832. There is nothing in medical biography so charming as this interchange of scientific interest between the young student, flushed with the excitement of his first great acquisition, and the sympathetic and receptive father in Boston, busy with a great practice and hospital and college duties.

The books were not offered for sale, but copies were sent by Dr. Jackson to his friends and many warm replies were received. My copy is addressed to “Reverend Sewell with Doctor Jackson’s respects.” About these memoirs, Dr. Henry Barton Jacob wrote “I scarcely know any book which is more of an inspiration to the medical students, more of an incentive to hard work and to high ideals, than the little story of the life of this young man.” Quoting Osler again, “I do not know in our profession of a man who died so young who has left so touching a memory.” His name, too, will always be associated with the studies on emphysema, and he is the discoverer of the prolonged expiratory sound in early pulmonary tuberculosis. Greater than these was the influence he exerted on American medicine through his immediate influence on the rising members of the profession of his generation in the habit of thorough observations of the phenomena of disease in the living and in the dead.

OLIVER WENDELL HOLMES (1809-1894)³⁷⁻³⁴

Another of the group which studied with Louis in Paris was Oliver Wendell Holmes, born August 29, 1809, at Cambridge, Massachusetts, one of the

*Marcellus married Julia, daughter of Augustus, after being adopted by Augustus. In line for the throne, he died at the age of twenty years in 23 B.C. He was praised by Virgil.

"Brahmin caste of New England From Phil lips Andover Academy, he entered Harvard in the famous Class of 1829

Turning to medicine, and convinced by a brief experience in Boston that he liked it, he went to Paris in March, 1833, to study. Returning to Boston at the close of 1835, filled with high professional ambition, he sought practice, but achieved only modest success because the grave Bostonians did not think him sufficiently serious. He won a prize, however, for professional progress and lectured on anatomy at Dartmouth. In 1843 he published his essay on the "Contagiousness of Puerperal Fever" which brought him bitter personal abuse, but in due time he was honored as the discoverer of a beneficent truth. The volume of his medical essays holds some of his most scintillating thoughts, his most shrewd observations, his most kindly interest in mankind.

In 1840 he married Amelia Lee Jackson, a cousin of James Jackson, and seven years later he was appointed professor of anatomy and physiology at Harvard, the duties entailing classes also in related departments so that as he said, he occupied not a chair, but a settee in the school. This position he held until 1882. His lectures were fresh, witty and lively, so that the students were sent to him at the end of the day, when they were fagged, since he alone could keep them awake. In later years he made few contributions to medical knowledge, his eager impetuous temperament caused him to leave more patient investigators to push to ultimate results, the suggestions thought out by his fertile and imaginative mind.

We all know him for his *Autocrat of the Breakfast Table* his "One Hoss Shay" and his "Chambered Nautilus." Fortunately, Dr. Holmes's medical essays are reprinted with his works. Several of them are enduring contributions to the questions with which they deal, all should be read carefully by every student of medicine. The essay on "Homeopathy" remains one of the most complete exposures of that therapeutic fad. There is no healthier or more stimulating writer for students and young medical men. With rare humor, with unflinching kindness and with a delicacy of feeling peculiarly his own, he has permanently enriched the literature of the race.

Eight years before his death he made a triumphal tour of Europe and received many degrees. He

died in 1894 and was buried from Kings Chapel, Boston, in the cemetery of Mount Auburn.

Search the ranks of authors since Elia, whom in so many ways Holmes resembled, and to no one else could the beautiful tribute of Landor be transferred with the same sense of propriety.

He leaves behind him freed from grief and fears,
Far nobler things than tears,
The love of friends without a single foe,
Unequaled lot below.

15315 East Jefferson Avenue.

PRESENT-DAY MEDICAL ECONOMICS^a

An Informal Discussion

REGINALD FITZ, M.D.†

BOSTON

IN 1928, Dr William S Thayer presented my name to the House of Delegates of the American Medical Association as a prospective member of the Council on Medical Education and Hospitals. The House duly ratified this suggestion, and since then I have followed carefully the business of the American Medical Association.

I found myself, *ex officio*, a member of the House of Delegates, and at my initiation into it at Portland, Oregon, in 1929, I attended a medical meeting unlike any other I had previously been to. Here I heard debated by delegates from all over the country a variety of subjects which hitherto had been taken pretty much for granted by my friends in Massachusetts, and yet which appeared to be of considerable concern to doctors from various other parts of the United States. It seemed peculiar, for instance, to bother over the fact that many colleges were beginning to conceive it their function to look after the physical welfare of their students and were establishing well-organized health departments. It seemed of little more than passing interest to be told that the cost of medical care was agitating the public and that in certain sections considerable criticism was being vociferously directed at the medical profession, the feeling being expressed that doctors themselves were largely responsible for the present unsatisfactory situation. Of course I knew that the Committee on the Costs of Medical Care had been organized, and I was acquainted with several of its members. I even looked forward to seeing its report. But I had not stopped to realize that this committee was financed by lay foundations, such as the Twentieth Century Fund, the Milbank Fund and the Rosenwald Fund, nor did I sense the profound influence that money played in the trend of medical philosophy. Since then my education has progressed. I have followed the proceedings of the House of Delegates with much interest, have sat regularly at its sessions and have acquired a kaleidoscopic impression of the confused state of American medicine, which I shall try to describe.

It is difficult to comprehend, if one is living in the midst of an economic thunderstorm, where the lightning strikes, what harm it does and what

scars may be left when the storm passes over. Yet I think everyone will agree that since 1929, and the stock-market crash, the medical profession has survived a violent hurricane, and that in all probability medical practice will never again be quite what it was before the cyclone struck.

In 1930, notable changes had already begun to develop as an aftermath of what was going on in the world. An important event had recently taken place abroad. A public medical-service association had been established in England with a view to setting up a universal medical service, government controlled and available to the entire population. This seemed a disturbing occurrence to certain farsighted people in this country who already knew that in Belgium a similar organization existed, and that doctors there were anything but happy working under it. New developments toward bureaucratic medicine were beginning to be seen here also, various corporations seemed to be entering the practice of medicine, public-health programs were expanding, veterans' legislation appeared to be excessively expensive, some \$30,000,000 had been appropriated within the year to look after veterans of the World War, and it looked as if the federal government soon contemplated going into general practice, particularly as it was constructing hospitals to accommodate veterans suffering from diseases and injuries in no way related to war service.

It was somewhat comforting to learn that the Committee on the Costs of Medical Care had come out with three fundamental principles unanimously agreed on by the entire committee: the personal relation between physician and patient must be preserved in any effective system of medical service, the concept of medical service in a community should include a systematic and intensive use of preventive measures in private practice and effective support of preventive measures in public health work, the medical service in a community should include the necessary facilities for adequate diagnosis and treatment. These three principles were entirely acceptable to the House of Delegates, since for years the American Medical Association had stood out strongly on the desirability of better medicine, and for maintaining the personal relation between doctor and patient.

The years 1932 and 1933, as one looks backward,

^aPresented at the Cambridge Hospital, Cambridge, Massachusetts, January 16, 1940.

†Lecturer on the history of medicine, Harvard Medical School.

were important to American medical economics chiefly because they marked the end of a Republican era in government and the beginning of a Democratic one, and because, politically speaking, they were years of pre-election jockeying. However, in 1932 the House of Delegates was informed that four hundred and thirty organizations in the country were offering or furnishing medical services on a contract basis, and thus it was apparent that experiments along such lines were being conducted busily enough. A new medical economic phenomenon also had appeared on the horizon. This was group hospitalization insurance. While the idea was comparatively new, it was growing rapidly. In fact, by 1933 more than thirty schemes had been proposed to provide for the prepayment purchase of hospital care.

The House of Delegates in 1932 and 1933 was a conservative body. I think that at each session the delegates felt that the financial losses which hospitals had suffered by depreciation in value of their endowments had led hospital trustees and superintendents to be willing to experiment with almost anything that might make both ends meet. In discussing group hospitalization plans in the early days, the opinion was often expressed that many of the proposals for the prepayment of hospital care were not altogether sound. Such proposals seemed on the whole to emanate from persons, not doctors, who were propagandists or promoters looking for profit. Little consideration was given to the personal relation between patient and physician. In certain of the plans, the insurance contracts tended to involve the services of the clinical pathologist, the anesthetist and the roentgenologist, with the implication that these services were at times being exploited to provide an income to the hospital by which to meet deficits in other departments.

And who could tell where the snowball of hospital insurance might roll or to what dimensions it might grow? How soon would the services of the surgeon, the obstetrician and the internist be included, and if so, what was to become of private practice and the personal relation between doctor and patient? How soon would someone in a well-padded political armchair say that voluntary hospital insurance was operating so successfully that compulsory insurance should be put in effect as soon as possible, and that this type of insurance should be placed in the hands of the federal authorities?

The year 1934 was an important one. Mr. Roosevelt had already been inaugurated as president. Shortly afterward, rumors began to circulate that the campaign for a socialized system of furnishing medical care to a large proportion of

the population was about to begin. In June, President Roosevelt announced his intention to propose legislation toward greater economic security for the people of the United States, and indicated, as a primary objective, the care of the unemployed and the aged. A few months later he went on to say that closely related to the broad problem of livelihood was added the problem of security against the major hazards of life: hence, he planned to make definite recommendations which should cover benefits for children, for mothers, for the handicapped, for maternity care and for other aspects of dependency and illness. Very soon the original Wagner bill was introduced, a bill advocating cash payment in partial replacement of wage loss due to sickness, and government controlled insurance for maternity and medical services.

The American Medical Association, before all this came about, had been studying the manner in which compulsory health insurance appeared to operate in those countries adopting it. So far as could be discerned, it did not, on the whole, operate too successfully. It appeared to place in government hands the practice of medicine; health insurance tended to become a political instrument used for the purchase of votes rather than an instrument for improving public health. The result was that the medical service rendered by health insurance tended to become perfunctory and to result in unnecessary treatment. The people who were insured were likely to try to get their money's worth by using doctors unnecessarily. Worst of all the guidance of medicine, of research and of teaching was liable to fall under political rather than professional control and this seemed dangerous to American medicine. For these reasons, early in 1935 at a special meeting, the House of Delegates opposed the Wagner bill and reaffirmed its opposition to all forms of compulsory sickness insurance.

The original Wagner bill was not passed, but another Wagner bill was to be introduced in 1939. Between 1935 and 1939 many things important to medical economics took place. From my own viewpoint, it seems to me that about this time a less conservative attitude in American medicine began to develop. At the meeting of the House of Delegates in 1935, we were told that there were on record seven hundred and forty-eight different schemes of contract practice, and that nearly two hundred different experiments were being conducted in different areas by county medical societies in an effort to organize a more equitable distribution of medical cost. These figures seemed to prove that a great deal of experimentation in medical economics was continuing. As one tries

eled around the country and talked to doctors, one heard it said, again and again, that unless the medical profession developed a feasible plan for the care of the American people, state medicine was inevitable. So keen an observer as the late Dr. J. Tait Mason remarked that there were, at that time, three classes of doctors in the United States: those who felt that the American Medical Association needed better leadership and were inclined to turn up their noses at the way in which the Association was doing things, those a little more cautious who believed that a change in medical care was coming, but who hoped that all that was good and worth while in the present scheme of medical practice might be preserved, and finally, those who admired the conservatism heretofore displayed by the House of Delegates. To these latter men, who seemed to be in the majority, the economic crisis of the last few years had been an unhappy experience, inevitably focusing undue emphasis on the financial aspects of medical work, and leading to rash experimentation or to hasty judgment. These conservatives wished to see preserved, at all costs, the individual private practice of medicine, with free and open competition among physicians and the maintenance of the personal relations between doctor and patient.

Time marched on, restlessness was fomented, experimentation toward socialized medicine continued. In 1935, bills were proposed in seven states looking toward the establishment of compulsory systems of state health insurance, and in 1936 bills were introduced in two more states for the same purpose. In 1937 there appeared, under the auspices of the American Foundation and largely from the pen of Miss Esther Lape, a two-volume book, *American Medicine: Expert testimony out of court*. This book summarized a recent questionnaire circulated among medical men on the organization of medical care in the United States, and was a carefully assembled piece of work. Various problems were discussed in it: the adequacy or inadequacy of medical care, medical education, group practice, state medicine, health insurance and other kindred topics. No conclusions were drawn, but the general tenor of these volumes appeared to show that the present state of medicine was not entirely happy.

I have no idea how many people read Miss Lape's book nor how much influence it had. Probably it attained no general popularity, and was studied not so much by the man in general practice as by the professor in the habit of diffuse reading and abstract thinking, or by persons interested in the theory rather than the practice of medicine.

It seems to me, on the whole, that this book acted like an enzyme, increasing the irritation of the small group of doctors likely to read it who

were by nature truculent, and either indifferent to or dissatisfied with the manner in which the American Medical Association did things. The upshot was that in the fall of 1937 a group of four hundred and thirty such physicians issued their "Principles and Proposals." The principles were four in number: that the health of the people is a direct concern of the government, that a national health policy directed toward all groups of the population should be formulated, that the problem of economic need and the problem of providing adequate medical care were not identical and might require different approaches for their solution, and that in the provision of adequate medical care for the population four types of agency were concerned—voluntary, local, state and federal agencies. The truth of these general principles being assumed, they were implemented by various proposals: preventive medicine should be emphasized, medical indigents should be cared for by public funds, medical education and research should be supported in part by the public treasury, public money should be made available to hospitals that rendered service to the medically indigent, in the allocation of public funds for hospital care, private institutions should be utilized to the largest possible extent, public-health services should be extended by evolutionary processes, and the whole function of the government in relation to health should be consolidated in one separate department.

The strength of the "Principles and Proposals" lay in the fact that they were advocated by honest men of the highest caliber, occupying positions of great responsibility, and with a reputation for leadership in their various provinces. The weakness lay in the fact that the ideas set forth by no means represented public medical opinion. Certainly the House of Delegates did not like them.

In 1938, the House of Delegates realized that new schemes for the organization and distribution of medical services were increasing rapidly, and by then was thoroughly conscious of the fact that the medical profession must play a part in seeking to solve economic problems in relation to illness. For at that time every thinking doctor realized that socioeconomic conditions had become inseparably interwoven with health and sickness and that medical practice had changed. The difficulty was to know exactly the wisest course to pursue.

The delegates felt certain that complete dominance of medical practice by government was unwise. To maintain a personal relation between patient and physician still seemed desirable. The country was so large that no two conditions of medical practice were alike in any two parts of it. No single experiment that had been conducted along the lines of hospital or group health insurance could serve as a model to the whole country.

Most plans on which information was available were conceived with the idea of offering low-cost medical services to special groups of persons. Thus there had grown up, in a comparatively short time and involving many people, a variety of insurance schemes: industrial medicine, health associations for groups of employees and their dependents, student health services, fraternal health associations and sundry other local health insurance plans. Surveys made to throw light on what occurred in the way of results from these endeavors showed that good medical service cost, on the average, twenty-five to thirty dollars per person per year. It seemed hardly possible that any arrangement could lower this average cost and at the same time do good work. Practically all the plans boiled down to being no more than arrangements by which doctors were induced to sell their services to a promoter, who, in turn, resold these services to prospective patients. How happily the doctor came out under any of these systems was not altogether clear, though doctors working for salaries did not seem to complain.

In theory, the idea of collecting the average annual cost of medical services from each of a number of persons, in the hope of relieving a few, is delightfully plausible. There are, however, several objections to it. In the first place, plans that depend on underbidding, advertising or solicitation are hardly to be justified, but how is a promoter to drum up trade without the use of such devices? In the second place, to many doctors the free choice of physicians by patients is desirable, though not so desirable as it had seemed a few years ago, because one of the striking findings of insurance surveys was that only rarely did the persons insured seem to care much whether they could or could not select their doctor. However, plans of insurance which paid medical bills and which permitted free choice of physician and free choice of hospital seemed to be no more expensive and no less efficient than were more exclusive plans in which the choice of physician or hospital was limited. In the third place, a charge must be added to the average cost to each person insured to provide for the administrative expenses in any insurance plan, and the cost of overhead may easily involve a considerable sum. In the fourth place, it is impossible to calculate in advance a premium that will provide for the cost of new developments in medical science, the result being an inevitable collision sooner or later between the resources of the insurance system and the needs of the insured person for new and indeterminate amounts for expensive medical care. The insurance, therefore, might soon cost more than it was worth. In the fifth place, each individual who buys insurance is likely

to try to get back his money's worth. In the sixth place, experience abroad has shown that voluntary organizations under medical control set up to perform the possible functions of a state system of medicine have always drifted inevitably, into compulsory insurance under government control. A skeptic like myself feels, as he hears of a new and successful experiment in group medical insurance, that one more solid brick has been laid on which soon the government will build the superstructure of compulsory health insurance.

The House of Delegates, today, is a different body than it was in 1929 when I sat in it for the first time. A variety of changes have occurred to make the ordinary doctor conscious of the medical economic revolutions through which he has lived in the past decade, and thoroughly sensitive to many influences which were imperceptible a generation ago.

A new Wagner bill was submitted in 1939. It was an offshoot of the so-called National Health Conference held in Washington in July, 1938.

There was a special meeting of the House of Delegates in September, 1938, when the program of the National Health Conference was debated. The delegates decided that several features of the program were admirable; one was unacceptable. They were, for example, sympathetic to the idea of establishing a federal department of health with a representative in the President's cabinet. They believed in efficient and economical expansion of public health or maternal and child health services only, however, so far as such expansion could not be successfully accomplished through the private practitioner. They believed in the expansion of general hospital facilities when need existed, pointing out the desirability of first using existing hospital facilities before erecting new buildings. They believed in the complete care of the medically indigent by tax funds administered by local governmental units. They accepted as useful the principle of hospital insurance, including hospital care only, and not including any type of medical care. They also accepted as useful the principle of cash indemnity insurance to cover the cost of emergency or prolonged illness, provided such schemes complied with state statutes and regulations to guarantee their soundness and the financial responsibility of their underwriters, and provided that they had the approval of the county and state medical societies under which they operated. They approved the principle of insurance against loss of wages during sickness. They did not approve of any system of compulsory health insurance.

When the Wagner Bill was finally written, it appeared a different bill than might have been

expected to develop from the results of the National Health Conference. It had a title which sufficiently stated its purposes: "A bill to provide for the general welfare by enabling the several states to make more adequate provision for public health, prevention and control of disease, maternal and child health services, construction and maintenance of needed hospitals and health centers, care of the sick, disability insurance, training of personnel and for other purposes." In brief, the bill provided federal subsidies through which to induce the states to undertake new activities, and to enlarge activities already under way in certain public-health and medical-service fields. A lot of hospital construction was to be undertaken. The bill proposed to spend \$98,000,000 in 1940, \$123,000,000 in 1941 and \$334,000,000 in 1942. While no specific mention was made of compulsory sickness insurance, the measure introduced the principle of allotment of federal money to individual states for medical care, and was silent as to whether such care should be provided through a state medical service or by a system of state health insurance or by payment of services on a fee basis. (Closely related to this act was the Capper Sickness-Insurance Bill, contemplating a federal appropriation of \$200,000,000 each year to induce the states to develop and maintain systems of health insurance.) None of the suggestions made as the result of the National Health Conference and supported by the House of Delegates appeared to have received much consideration. In fact, the bill appeared bizarre, and contrary in almost every way to the best interests of the health of the American people. The House of Delegates believed that each member of the American Medical Association should oppose it.

Thus, we reach the year 1940 with medical economics still in an unsettled state. The trustees have recently constructed a platform as a guide to indicate the trend which the American Medical Association believes should be followed in the development of health activities and medical care for the people of the United States. The platform

appears fairly to represent what most doctors agree to. It is a simple affair. It advocates the establishment of an agency of federal government under which will be co-ordinated all medical and health functions of the government. It advocates the allotment of such funds as Congress may make available to any state in actual need for the prevention of disease, for promotion of health and for the care of the sick. It advocates the development of a mechanism to expand preventive medical services and to extend medical care for the indigent, with local determination of needs and local control of administration. It advocates the expansion of public-health and medical services in a manner consistent with the American system of democracy. It advocates the utmost utilization of qualified medical and hospital facilities already established. It advocates the continued development of the private practice of medicine. It deplores the introduction of methods such as compulsory sickness insurance or state medicine.

Possibly the last decade has done the medical profession good rather than harm. Certainly, doctors have grown more mindful of the social relations in their work and of the importance of medicine to public welfare. They have become more open-minded, less uncompromising, entirely willing to experiment with plans by which to take care of the indigent and to reduce the cost of medical care. They have become glad to co-operate with the Government in improving public health measures. No longer are they too proud to face the fact that others besides themselves have a stake in the advance of medical education and medical research. The average doctor, however, still believes that medicine is an art and not a trade, that the personal relation between physician and patient is important and that any form of compulsory health insurance will retard the advance of medical knowledge. How much longer the medical profession will maintain its high ideals of self-sacrificing, uncommercial service is a question.

THE DIAGNOSIS AND TREATMENT OF SIGMOIDAL POLYPS*

RICHARD B. CATTELL, M.D.,† AND NEIL W. SWINTON, M.D.‡

BOSTON

IN RECENT years, considerable attention has been directed to cancerous lesions of the large intestine, and although different types of operations have been employed, the principle of radical removal has been accepted as yielding the best results. Insufficient attention has been paid to the diagnosis and treatment of intestinal polyps, the premalignant lesions, for which radical resections are seldom necessary. It is for this reason that we wish to present our experiences with 10 patients operated on for sigmoidal polyps during the last

Swinton and Warren§ have recently reported the above mentioned series of 156 patients with benign and malignant polyps of the colon and rectum. During the period that these patients were observed, 827 patients were operated on for carcinoma of the colon or rectum. A careful study of these removed lesions showed that 120 (14 per cent) could be proved histologically to have arisen from benign mucosal polyps. In 35 per cent of the cases more than one polyp was found. The polyps were located in the rectosigmoid and rec-

TABLE 1 Summary of Data in 10 Patients with Sigmoidal Polyps

| CASE NO. | AGE | SEX | DURATION OF SYMPTOMS | PRESENT SYMPTOM | MEANS OF DIAGNOSIS | OPERATION | DATE | PATHOLOGICAL REPORT | FOLLOW-UP REPORT |
|----------|-----|-----|----------------------|-----------------------|---|---|----------|--|---|
| 1 | 48 | F | 3 yr. | Bleeding | Sigmoidoscopy, barium enema | Sigmoidectomy | 12/7/32 | Mucosal polyp | Operation for carcinoma of transverse colon on July 3, 1937; other polyps in January 1939 |
| 2 | 68 | F | 9 mo. | Bleeding, diarrhea | Sigmoidoscopy, barium enema | Sigmoidectomy | 10/28/33 | Malignant adenoma | Well in January 1938 |
| 3 | 63 | M | 3 mo. | Bleeding | Sigmoidoscopy | Sigmoidectomy | 1/29/38 | Adenocarcinoma in mucosal polyp | Well on March 15, 1939 |
| 4 | 37 | M | 2 1/2 | Bleeding | Contrast enema | Sigmoidectomy | 5/7/38 | Mucosal polyp | Well on February 21, 1939 |
| 5 | 53 | M | 1 yr. | Bleeding | Sigmoidoscopy | Sigmoidectomy | 5/9/38 | Mucosal polyps with precancerous foci | Well on July 6, 1939; two other polyps surgically |
| 6 | 70 | M | 6 mo. | Bleeding, obstruction | Clinical | Sigmoidectomy | 9/2/38 | Mucosal polyp with focus of malignancy | Well on April 20, 1939 |
| 7 | 75 | M | 15 1/2 | Bleeding | Sigmoidoscopy | Sigmoidectomy | 9/16/38 | Mucosal polyp | Well on February 2, 1939 |
| 8 | 60 | F | 3 yr. | Bleeding | Clinical (sigmoidoscopy twice negative, barium enema, twice negative) | Sigmoidectomy | 10/27/38 | Adenocarcinoma in polyp | Well on August 24, 1939 |
| 9 | 49 | F | 6 yr. | Bleeding | Sigmoidoscopy | Sigmoidectomy | 3/11/39 | Mucosal polyp | Well on July 26, 1939 |
| 10 | 35 | F | 3 mo. | Bleeding, diarrhea | Clinical (barium enema negative) | Sigmoidectomy, supracervical hysterectomy, left salpingo-oophorectomy | 5/1/39 | Mucosal polyp endometriosis | Well on June 1, 1939 |

seven years. During the same period 156 patients with polyps of the colon and rectum were treated, so that the group considered in this paper represents but six per cent of the total cases. The surgical problems incident to treatment of polyps in the colon are quite different from the treatment of those occurring in the rectum below the pelvic peritoneal reflection. The method of treatment of the sigmoidal polyp is the same as that for those occurring in other portions of the colon even though they are infrequent in the proximal portion of the large intestine.

During the same period 156 patients with polyps of the colon and rectum were treated, so that the group considered in this paper represents but six per cent of the total cases. The surgical problems incident to treatment of polyps in the colon are quite different from the treatment of those occurring in the rectum below the pelvic peritoneal reflection. The method of treatment of the sigmoidal polyp is the same as that for those occurring in other portions of the colon even though they are infrequent in the proximal portion of the large intestine.

The frequent occurrence of cancer in patients having congenital polyposis of the colon has long been recognized. In 1932 we proctoscoped 5 adults of one family between the ages of thirty-one and thirty-nine, and found 4 to have congenital polyposis. Three of these subsequently died of cancer, and a fourth died postoperatively following complete colectomy. Two patients had

§Swinton, N. W., and Warren, S. H. Polyps of the colon and rectum and their relation to malignancy. *J. M. A.* 113:197, 1935, 1939.

multiple malignant foci Within the last six months we have had 2 patients with multiple cancers found at the time of operation, which we believe arose from different polyps One patient had a carcinoma of the splenic flexure and of the sigmoid, while the second had a carcinoma of the cecum and of the transverse colon The routine examination of resected specimens for carcinoma very frequently shows one or more polyps in addition to the cancer A further point substantiating the occurrence of cancer in polyps has been observed in a comparison of the positions of polyps and of cancer In the large series, 68 per cent of the polyps were found in the rectosigmoid and rectum and approximately 60 per cent of the carcinomas of the large intestine observed at the Lahey Clinic occurred in the same location

Bleeding was the presenting symptom in all 10 cases with sigmoidal polyps In 6 cases bleeding had been present for one to fifteen years One patient had symptoms of a moderate obstruction because of the size of the polyp A disturbance of bowel function is unusual and should suggest the presence of malignancy The other symptoms presented by the patients in this series were due to the presence of other conditions

The demonstration of polyps in the sigmoid colon may at times be quite difficult The same diagnostic methods that are used for malignant lesions of the intestine must be employed Proctoscopic and sigmoidoscopic examinations prove of the greatest value, since other polyps may be visualized in the rectum and rectosigmoid, and frequently the sigmoid polyp will be seen It is quite important that these patients be properly prepared before one attempts to carry out sigmoidoscopic examination They should receive 30 or 60 cc of castor oil the evening before examination This is to be followed by cleansing enemas the following morning It is best to have the patient in an inverted position so that the rectosigmoid will become straightened by gravity and the instrument can be passed into the lower sigmoid Close examination of every portion of the mucosa is essential if the small sessile polyps are not to be missed

Following the sigmoidoscopic examination, with the benefit of the preparation stated above, a barium enema is given If the presence of a polyp is suspected, a double-contrast air enema will probably be necessary in order to demonstrate the discrete polyp One x-ray examination may not be successful in outlining the polyp, and in our experience repeated studies have at times been necessary These two methods may not prove the presence of a sigmoidal polyp, even though the history of bleeding is strongly suggestive of its presence In 2 of our 10 cases, abdominal exploration

was carried out to demonstrate the presence of a polyp

The methods of diagnosis, when taken with the clinical story, should be sufficient to exclude the other organic lesions that may be found in the colon One of our patients was operated on with the diagnosis of cancer of the colon, and it is our belief that we cannot exclude cancer in any of these cases preoperatively Ulcerative colitis, diverticulitis, endometriosis with obstruction, benign lesions and tuberculosis, as well as local anorectal conditions and amebic and bacillary dysentery, must be excluded

The treatment of rectal polyps discovered by this routine investigation is a much simpler problem

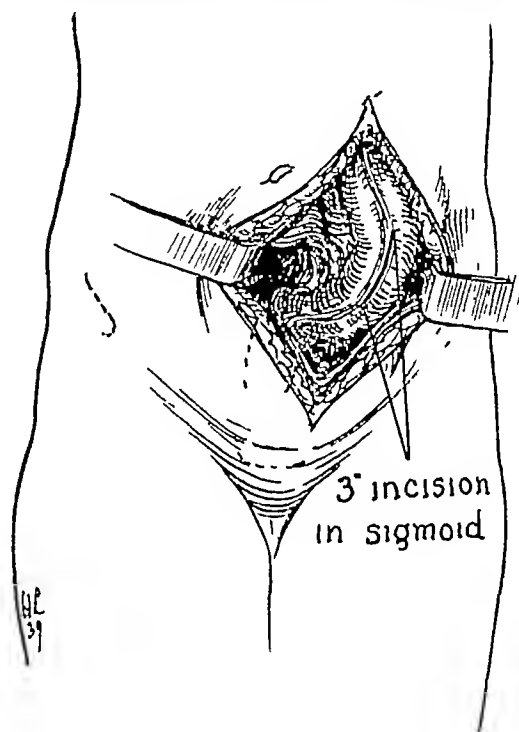

FIGURE 1

The line of incision is made in the longitudinal band

Those below the pelvic peritoneal reflection can be fulgurated under direct vision in one or more stages The patients must be carefully examined subsequently in order to be certain that the mucosa is completely healed It is our strong belief that all polyps in any part of the large intestine, irrespective of size, should be destroyed or removed Those above the pelvic peritoneal reflection can be fulgurated successfully if great care is exercised to avoid perforation and bleeding A long, pedunculated polyp must have the pedicle coagulated by the slow current in order to avoid hemorrhage In 1 of our cases with a high rectosigmoidal polyp serious hemorrhage occurred, necessitating packing of the bowel and later fulguration, two transfusions were necessary for this patient Perforation occurred in 1 case but did not result fatally Signs

of peritoneal irritation are not uncommon, and all these patients should be hospitalized if fulguration is to be done for polyps above the reflection of the peritoneum.

The treatment of sigmoidal polyps is a more serious problem. Hemorrhage following sigmoidoscopic treatment is difficult to control at this level. The danger of perforation of the colon above the peritoneal reflection is evident. It is technically difficult to remove or destroy large sigmoidal polyps through the sigmoidoscope. The problem of dif-

ferentiating the malignant and the benign polyp in the sigmoid should be as close as possible to this position. A longitudinal incision is made through a longitudinal band after carefully walling off this portion of the sigmoid (Fig 1). The incision should be long enough to examine the mucosa for a considerable distance, 3 cm. usually being sufficient. If there is cancerous infiltration of the base or pedicle, the incision in the sigmoid should be closed and resection carried out as for any cancer. If the pedicle is free, the polyp is excised with a generous portion of the mucosa at its base. The mucosal defect need not be sutured. The incision in the sigmoid is then closed with fine, interrupted, silk sutures in two layers (Fig 2). In 4 of our cases this suture line was reinforced with the appendices epiploicae, and in 1 case the entire incision was made extraperitoneal by reflecting a flap of peritoneum from the lateral wall. If the

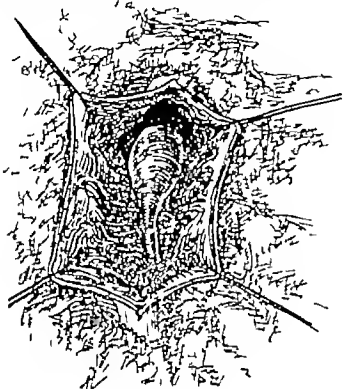

FIGURE 2.

Following the isolation of the operative field with gauze the sigmoid is opened thus exposing the polyp with its base.

ferentiating the malignant and the benign polyp is difficult in this region. Because of these facts we believe that sigmoidal polyps should be removed at laparotomy. The 10 patients in our series had laparotomy with sigmoidotomy. Spinal anesthesia was used for all cases, with a 10 per cent Pontocaine solution—14 to 18 mg. This type of anesthesia provides the best possible operating conditions.

Thorough exploration of the entire colon should first be carried out. If a satisfactory preoperative preparation of the colon has been obtained, there should be little confusion of polyps with fecal masses. They may also be confused with diverticula, but the fixation of the latter in one location and their appearance should make identification possible. Polyps can be palpated through the sigmoidal wall and moved back and forth within the lumen. Induration or fixation of the polyp makes the diagnosis of cancer imperative, necessitating resection. If tension is made on the polyp a dimpling can usually be demonstrated at the point of attachment of the pedicle, and frequently the pedicle itself can be felt. It is important to identify the site of the pedicle, since the incision

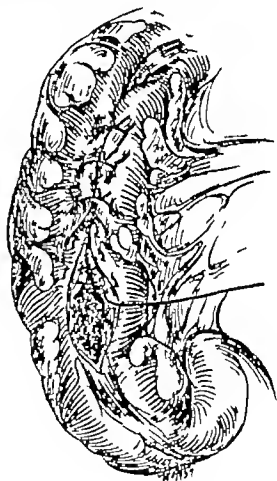

FIGURE 3.

The incision in the wall of the sigmoid is closed with two sets of sutures.

suture line is not satisfactory it should be made extraperitoneal.

Thorough histological study was made of the twelve polyps removed from these 10 patients by sigmoidotomy. One showed a malignant adenoma, and two an adenocarcinoma. Two others contained small foci of malignant change. In none was there any evidence of extension into the pedicle, and in no case could cancer be determined from the gross appearance. Based on our opinion on this experience, we believe that when on complete histological study no evidence of invasion of the pedicle or base is found, radical resection for polyps of this type is unnecessary. The occurrence

of early malignant changes in 5 of the 10 cases is striking evidence of the importance of the removal of all sigmoidal polyps as soon as they are discovered

The postoperative convalescence was satisfactory in all cases, there being no complications and no mortality

All polyps that could be visualized distal to the point from which the sigmoidal polyps were removed were destroyed by fulguration. One patient (Case 1) developed a carcinoma in the transverse colon just distal to the hepatic flexure four and a half years after sigmoidotomy. This was

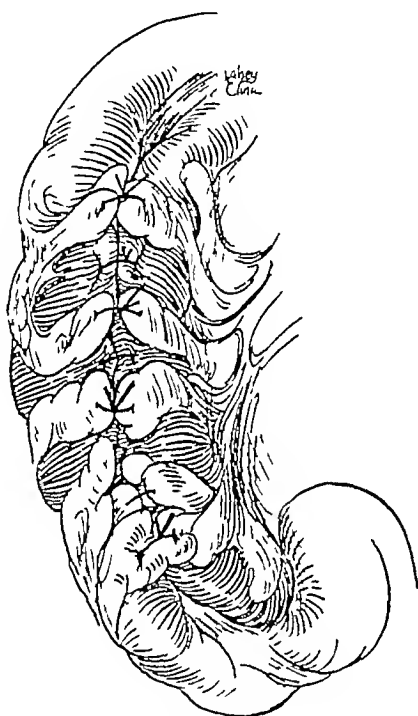

FIGURE 4

The wound is reinforced by suturing appendices epiploicae across the line of the incision

successfully resected by a modified Mikulicz type of resection. The other 9 patients remained well for the period of observation.

Patients who have had polyps in the large intestine should be kept under observation for an indefinite period. Sigmoidoscopic examinations and contrast enemas should be done each year for at least five years. Judging from our experience with carcinoma of the large intestine we believe that observation should be carried out for the same period postoperatively, since these patients are more apt to have subsequent cancer in other portions of the colon than are normal individuals. We have been mainly concerned in the past with observing such patients at regular intervals in order to discover the presence of distant metastases, particularly in the liver, whereas we should be equally concerned with the possible development of a new lesion in the bowel itself.

CASE REPORTS

CASE 1 E W, a 48 year-old, married woman, was first admitted in April, 1929, complaining of symptoms typical of peptic ulcer and rectal bleeding of several years' duration. Complete gastrointestinal x ray and laboratory studies without proctoscopic examination showed a duodenal ulcer. Dietary treatment for ulcer was carried out and the ulcer symptoms were relieved. Rectal bleeding, however, continued. In April, 1930, sigmoidoscopic examination showed two small mucosal polyps at the rectosigmoid juncture for which no treatment was advised. No hemorrhoids or other local anorectal disease was seen.

In December, 1932, because of continued rectal bleeding, contrast air films of the colon following a negative barium enema showed a large, discrete polyp in the upper sigmoid. On December 7 sigmoidotomy and left salpingo-oophorectomy were performed. At operation, palpation of the sigmoid revealed a freely movable, walnut sized tumor, which was attached to a rather long pedicle. A longitudinal incision of the sigmoid was made and the polyp exposed. It was soft and friable and bled easily, and was excised, together with its pedicle. The bowel wall was closed longitudinally, and the suture line reinforced with appendices epiploicae. The left tube and ovary were removed because of the presence of a simple cyst. Pathological examination showed mucosal polyp. Postoperative convalescence was uneventful.

The patient next returned in June, 1937, because of increasing constipation. Barium enemas demonstrated a polypoid lesion in the transverse colon. On July 3 a Mikulicz type of resection of the right colon and right half of the transverse colon was performed. The pathological report showed adenocarcinoma and in addition two benign mucosal polyps. Postoperative convalescence was uneventful. The temporary colostomy was closed 2 months later.

In January, 1939, the patient was having some upper abdominal distress at times, but in general was in excellent condition.

Comment This case is an excellent example of the development of cancer in a patient known to have polyposis of the colon.

CASE 2 L P, a 68-year-old, married woman, was first examined October 10, 1933. The chief complaints were diarrhea and bloody stools of 9 months' duration. Sigmoidoscopic examination revealed a polyp in the lower sigmoid, 2 cm in diameter. Barium enema x ray and contrast air films of the colon were negative.

Sigmoidotomy was performed October 28. At operation a freely movable, walnut sized tumor in the lower sigmoid was palpable. A longitudinal incision in the bowel was made. The tumor was found to be a discrete, freely movable polyp with a long mucosal pedicle. The tumor and pedicle were excised, the bowel wall was closed longitudinally and the abdominal wall closed in layers. Pathological examination showed a malignant adenoma.

The last report from this patient was September 1, 1936, at which time she was perfectly well in every way.

CASE 3 L R, a 63-year-old man, was first examined January 27, 1938, for a chief complaint of rectal bleeding of 2 months' duration. Sigmoidoscopic examination demonstrated a discrete polypoid tumor in the lower sigmoid.

Operation was performed January 29. Palpation of the sigmoid revealed a discrete, freely movable tumor 11 cm. above the peritoneal reflection, with an unusually long pedicle. A longitudinal incision was made in the sigmoid and the polyp exposed. The tip was gangrenous and

was the obvious source of bleeding. The pedicle was 3 cm. in length. The polyp together with its pedicle was removed by the actual cautery. The bowel wall was closed in the longitudinal direction and the line of suture was reinforced with omentum. Pathological examination showed adenocarcinoma arising in a mucosal polyp. Because of the length of the pedicle of this tumor and its obviously benign character it was felt that simple removal was adequate.

Sigmoidoscopic examination made March 15 1939 was negative.

CASE 4 M.S., a 37-year-old man was first examined April 25 1938 because of rectal bleeding of 2 years duration. Sigmoidoscopic examination for a distance of 27 cm. was entirely negative. Barium enema and contrast air films taken after adequate preparation revealed a discrete polyp in the upper sigmoid, and also several areas in the transverse colon that were suggestive but not diagnostic of additional polyps. Re-examination the following day after further preparation of the bowel with castor oil and enemas, corroborated the findings of the sigmoid polyp, but showed that the additional defects in the transverse colon had disappeared.

Operation was performed May 7. Palpation of the sigmoid revealed a polyp 2 cm. in diameter and freely movable, in the midsigmoid. It was delivered through a longitudinal incision and was attached to a pedicle 1.5 cm. in length made up of normal-appearing mucosa. The polyp was clamped and removed and the bowel wall closed in a longitudinal direction. Pathological examination showed a benign mucosal polyp.

On February 21 1939 a sigmoidoscopic examination barium enema and contrast air films showed the entire colon to be negative.

CASE 5 L.Z., a 53-year-old man was first examined May 5 1938, because of rectal bleeding of 1 year's duration. Sigmoidoscopic examination showed a large polypoid lesion with a fairly broad base, 27 cm. from the anal margin. Biopsy showed it to be a benign polyp.

Operation was performed May 9. Palpation of the sigmoid revealed two polypoid masses, one at the midsigmoid and one at the rectosigmoid junction. Both tumors were freely movable. Both polyps were attached by benign pedicles, which were removed, together with the polyps. The sigmoid was closed in a longitudinal direction and reinforced with omentum. Pathological examination showed mucosal polyps with precancerous foci. Convalescence was uneventful.

Proctoscopic examination made July 6 1939 revealed two small mucosal polyps one 10 cm. and the other 17 cm. from the anal margin which were fulgurated.

Comment It is interesting to note that the polyps found at the time of the last examination had not been observed before, although a very careful examination had been made of this area 15 months previously.

CASE 6 H.H., a 70-year-old man was first examined August 29 1938 because of intermittent bleeding and increasing constipation of 6 months duration. Physical examination revealed slight lower-abdominal distention. A clinical diagnosis was made of an obstructing lesion in the sigmoid based on the presence of blood coming down from the sigmoid as seen through the sigmoidoscope.

Operation was performed September 2. Palpation of the sigmoid revealed a freely movable tumor in the descending colon 3 cm. in diameter which was exposed by a longitudinal incision in the bowel. The tumor was attached to a rather short but apparently benign pedicle and was removed together with its pedicle. The bowel wall was closed in a longitudinal direction. Pathological

examination showed a mucosal polyp with a focus of cancer. Convalescence was uneventful.

The patient reported April 20 1939 that he was in excellent condition without intestinal symptoms.

CASE 7 M.M. a 75-year-old man was first examined July 7 1938, primarily because of scatica but with a history of intermittent rectal bleeding of 15 years duration. Abdominal exploration in 1934 had shown no pathologic change in the colon. Barium enema showed a questionable small filling defect at the rectosigmoid. Sigmoidoscopic examination revealed a polyp at this point.

Operation was performed September 16. Palpation of the sigmoid revealed a freely movable, soft tumor in the lower sigmoid attached by a long thin pedicle. The tumor was delivered through a longitudinal incision and removed together with its pedicle. The colon was closed in a longitudinal direction and the suture line extraperitonealized. Pathological examination showed a mucosal polyp. Convalescence was uneventful.

Proctoscopic and barium enema x-ray films of the colon taken February 9 1939 were negative.

CASE 8 L.M. a 60-year-old married woman, was first examined October 21 1938 because of rectal bleeding of 3 years duration. Two barium enema x-ray studies of the colon were negative. Two sigmoidoscopic examinations for a distance of 25 cm. from the anal margin revealed blood in the lower sigmoid but no evidence of organic disease. A clinical diagnosis was made of benign or malignant polyp of the left colon.

Operation was performed October 27 1938. Palpation of the sigmoid revealed a freely movable polyp 2 cm. in diameter attached to a long pedicle with a broad base. A longitudinal incision in the sigmoid revealed the polyp to be friable, soft and apparently benign. The pedicle was clamped at its base and the pedicle and tumor were excised. A longitudinal closure of the bowel wall was made, reinforced by the appendices epiploicae. Pathological examination showed a mucinous adenocarcinoma arising in a mucosal polyp. Histological study of the pedicle showed it to be entirely benign and a resection was not felt indicated. Convalescence was uneventful.

A sigmoidoscopic examination barium enema and contrast air films taken August 25 1939 were negative.

CASE 9 P.P. a 49-year-old married woman, was first examined March 2, 1939 because of rectal bleeding of 6 years duration. Barium enema and contrast air films taken on two occasions were negative. Visualization of the lower sigmoid showed a polypoid tumor 4 cm. in diameter. A specimen taken at biopsy was reported as a benign mucosal polyp.

Operation was performed March 11. A soft, freely movable large polyp in the lower sigmoid was palpated. This was removed together with its base through a longitudinal incision. A smaller polyp lying 2 cm. proximal to this was also found at operation and removed in a similar manner through the same incision. The sigmoid was closed in a longitudinal direction. Pathological examination showed benign mucosal polyps. Convalescence was uneventful.

Sigmoidoscopic examination, barium enema and contrast air studies made July 26 1939 were negative.

CASE 10 I.F. a 35-year-old married woman was first examined April 17 1939 because of a bloody diarrhea of 3 months duration. A barium enema was negative. Sigmoidoscopic examination for a distance of 20 cm. from the anal margin revealed blood coming down from the bowel above this point, but no organic lesion was seen. A clinical diagnosis of polyps of the left colon was made.

Operation was performed May 1. Palpation of the sigmoid revealed a freely movable soft polyp 2 cm. in di-

ameter, in the midsigmoid region. The remainder of the pelvis revealed an extensive endometriosis. A supravaginal hysterectomy and left salpingo-oophorectomy were performed. The sigmoid polyp was then delivered through a longitudinal incision in the midsigmoid. It was attached to a long and benign mucosal pedicle. The polyp together with its pedicle was removed, and the bowel wall was closed in a longitudinal direction. Pathological examination showed endometriosis of the myometrium and a benign mucosal polyp. Convalescence was uneventful.

The patient reported by mail September 15, 1939, that she felt well and had had no intestinal symptoms.

SUMMARY

Ten cases of sigmoidal polyps are reported. Five of the twelve polyps removed showed early malignant changes. The development of cancer from benign mucosal polyps in the colon and rectum is discussed.

Rectal bleeding of unexplained origin suggests the presence of a sigmoidal polyp. Bleeding was the presenting symptom in all our cases. The diagnosis is made by sigmoidoscopic examination, barium enema and contrast air studies.

Sigmoidal polyps should be removed by sigmoidotomy rather than by fulguration through the sigmoidoscope, because of the danger of hemorrhage, perforation and technical difficulties, and because of the difficulty in excluding cancer.

The technic of operation is described.

There was no operative mortality. In 1 case, cancer subsequently developed in the transverse colon. The rest of the patients remained well. Careful follow-up observations by sigmoidoscopic and x-ray studies are recommended.

605 Commonwealth Avenue.

DISCUSSION

DR HOWARD M. CLUTE, Boston. One of the early examinations of the American Board of Surgery contained a question which read about as follows:

A man of fifty noticed bleeding from the rectum, and on examination was found to have a rectal polyp. It was removed with a proctoscope, and frozen-section examination showed no cancer. In five or six days, however, when the microscopic studies were more complete, the pathologist noted malignant degeneration. What would you do?

When the board met, someone said, "One of the first things we have to settle is what is the right answer to Question 6." There was a difference of opinion among the members. Some said that they would observe this patient and put radium in the base of the lesion, or cauterize it and proctoscope him every three months. Others felt strongly that he should have immediate abdominoperineal resection of the rectum, since, if there was ever hope of curing cancer of the rectum, this was an ideal case.

I think all of us, when we see a polyp, are very anxious to limit ourselves to removal with a snare or cautery, because we hate to subject the patient to an abdominoperineal resection. However, if there is the slightest question of cancer he must have a radical resection. When one is actually confronted with a case of this sort, however, with such a tiny lesion, it may be difficult to make oneself perform this radical procedure.

I recently examined a patient who a year before had had a small polyp in his rectum, which was removed elsewhere and showed a trace of cancer. When I saw him he was in an inoperable state with cancer of the rectum. Remembering this, when another patient came to me recently with a tiny polyp in her rectum and a biopsy showed adenocarcinoma, I decided on an abdominoperineal resection. The rectum on removal showed a small cancer with no evidence of any metastases. She should be cured, I believe.

This is a most important subject, and Dr. Cattell has covered it quite completely. I think the point he would emphasize, and I should emphasize, is that if one removes a benign polyp one is in danger of having left behind a cancer. The follow-up studies that Dr. Cattell mentions as being done routinely are extremely essential in all these cases.

DR ARTHUR W. ALLEN, Boston. I wish to emphasize one of the statements which Dr. Cattell has made. One must not try to remove these sigmoidal polyps from below. If one uses a small loop for lesions above the pelvic floor, one is very likely to get into trouble, as the loop may easily burn through the bowel into the peritoneal cavity.

So far as the radical operation on these early cases of cancer of the bowel is concerned, I am absolutely in accord with Dr. Clute. If we are to cure cancer of the bowel these early lesions must be attacked radically. It is perfectly true that some patients with low-grade cancer in a polyp in the colon or rectum may not develop a recurrence in later life if a simple removal of the polyp is done. On the other hand, the polyps certainly recur on occasion, and I believe that our best opportunity to cure this disease is in the early cases.

I was interested in Dr. Cattell's statement concerning the ratio of large bowel lesions to rectal lesions. He asserts that they have approximately 3 cases of large bowel carcinoma to 7 of carcinoma of the rectum. In a recent series of such cases that I have just begun to study at the Massachusetts General Hospital, we found 634 cases of carcinoma of the colon to 818 cases of carcinoma of the rectum. Thus you see we have a ratio of 6 to 8. In the *United States Public Health Service Reports* for 1936 there were recorded approximately 15,000 deaths from carcinoma of the colon, as against less than 8,000 deaths from carcinoma of the rectum. I believe the answer to this variation is that at present more surgeons will operate on patients with carcinoma of the colon than will undertake the combined abdominoperineal operation for carcinoma of the rectum.

One other question is that of Devine's defunctioning operation prior to the removal of a lesion lower down in the colon. This procedure is becoming popular, and I should like to suggest that we try to make our defunctioning colostomies, if possible, in the left upper quadrant, using the splenic flexure, and leaving the right upper quadrant free of adhesions, since this area may be needed for surgery on the gall bladder or stomach later in life.

DR CATTELL (closing). The published figures on the site of polyps of the large intestine vary greatly, probably because there is no uniformity in dividing the large intestine into the colonic and rectal segments. In our figures we include rectosigmoidal with rectal polyps, and this accounts for the high proportion reported in this area.

Dr. Allen and Dr. Clute have emphasized the importance of resection in cases of definite carcinoma even though it is early carcinoma. We are in complete agreement with this. However, if the cancer is confined to the periphery of the polyp and the pedicle is negative, complete excision of the polyp will be sufficient if these cases are followed carefully.

THE TREATMENT OF RHEUMATOID ARTHRITIS WITH SULFUR*

A Critical Evaluation

NATHAN R. ABRAMS, M.D.,† AND WALTER BAUER, M.D.‡

BOSTON

PATIENTS with chronic diseases of unknown etiology are frequently subjected to various therapeutic procedures that are of questionable merit and are usually based on conjecture. Such supposedly curative or ameliorative measures are regularly administered to patients with chronic rheumatoid arthritis, often at considerable expense, not infrequently with resulting complications, occasionally even death, and generally without material benefit to the patient. This state of affairs is due in part to the fact that patients with chronic diseases often demand treatment. They are ever hopeful that each new form of therapy prescribed will be as specifically curative as the adverse claims. There are, however, other causes for the continued prescribing of many useless anti-rheumatic remedies. The premature publication of poorly controlled studies acclaiming great therapeutic benefit and voluminous medical advertising constantly confront the busy practitioner of medicine. He possesses neither the time nor the facilities to investigate adequately the claims made. Except for the reports of the Council on Pharmacy and Chemistry of the American Medical Association, its "Queries and Minor Notes" columns and the all too infrequent publications concerning the repudiation of previously published premature claims, the busy physician has no way of determining the respective merits of many of the therapeutic procedures.

The parenteral administration of colloidal sulfur represents one of the more recently advocated forms of therapy for patients with rheumatoid arthritis, and has been acclaimed by many.¹⁻¹² Favorable results have been reported in 30 to 100 per cent of the cases so treated.¹⁻¹² Excerpts from some of these reports read as follows: "good results"—"a valuable agent in the treatment of certain types of arthritis"—"All the cases were objectively improved as judged by subsidence of swelling, relief of muscle spasm, decrease of thickening of joint capsule (when palpable), disappearance of any increased local temperature, de-

crease in tenderness, increase or return to normal range of motion and decrease in deformity." Woldenberg⁴ observed improvement in all of 250 patients with rheumatoid arthritis so treated. He reports disappearance of pain and muscle spasm following the fifth or sixth injection, and disappearance of joint effusions after the third or fourth week. Such enthusiastic reports naturally attract the attention of physicians. In fact, many might think that they were guilty of neglect if they withheld such supposedly beneficial therapy from their patients with rheumatoid arthritis. The physician's suspicion of the newly heralded rheumatic remedy should be aroused when he learns that therapeutic benefits are observed in patients with either degenerative joint disease (hypertrophic arthritis or osteoarthritis) or rheumatoid arthritis. These two types of arthritis are distinct disease entities, in no way causally related. Therefore, it would be most surprising to learn that the same therapeutic agent cured both diseases. A few reports concerning sulfur therapy have been unfavorable.¹³⁻¹⁵ In such publications, one reads such comments as "absolutely without effect," and "little or no improvement."

Recently, evidence has been presented in an attempt to place the treatment of rheumatoid arthritis with sulfur on a rational basis. This evidence has included an increased sulfur excretion,^{9, 19, 20} a reduced cystine content of the finger nails,^{2, 4-6} a decreased sulfur content in the articular cartilage²¹ and the need for a detoxifying agent.¹² Despite the presentation of these data, it will be shown that it is still impossible to prove the existence of a primary disturbance in sulfur metabolism in patients suffering with rheumatoid arthritis.

A negative sulfur balance was observed in 2 patients with rheumatoid arthritis, carefully studied by Goldthwait, Painter and Osgood.¹⁰ No control subjects were similarly studied. Cawadias⁹ reports an increased urinary excretion of sulfate, phenylsulfates and incompletely oxidized sulfur in all cases of "subacute rheumatism studied. Race,²⁰ however notes an increased excretion of unoxidized sulfur in only 20 of 42 cases of 'rheumatoid conditions,' all of which showed positive sulfur balances. This author stresses the fact that the above finding was difficult to interpret because

of failure to study comparable controls. Subsequently, Senturia²² was unable to demonstrate either an abnormal partition or the excretion of sulfur in the urine of arthritic patients.

The finding of a reduced cystine content in the fingernails has been cited repeatedly as signifying the existence of a sulfur deficiency.^{1 4-6 8 23} Many of the earlier reports¹³ concerning this abnormality are of questionable significance because of the method used in making such determinations. The fact that patients suffering from other diseases—carcinomatosis, prolonged fevers and so forth—exhibit lowered cystine content of the fingernails should cause one to be extremely skeptical of the value of such determinations in judging either the indication for, or the benefits to be derived from, sulfur therapy. Furthermore, some workers^{13 24} have stated that a large percentage of patients with rheumatoid arthritis do not show this abnormality. In addition, it has been claimed that rheumatoid arthritic patients may improve with sulfur therapy, even though the fingernail cystine content was normal, or failed to return to normal when such treatment was administered.¹³ Race²⁵ was the first to suggest that this phenomenon did not represent a primary disturbance of sulfur metabolism. He called attention to the fact that the cystine content of globulin was lower than that of albumin. This being the case, he thought it extremely probable that the reduced cystine content of the fingernails was a reflection of the altered plasma proteins, namely a reduced albumin-globulin ratio, so frequently observed in patients with rheumatoid arthritis.

The evidence suggesting that the sulfur content of articular cartilage is reduced in patients with rheumatoid arthritis is meager and not well established.²¹ Despite this fact, one author⁸ has suggested, without further proof, that at least some, if not all, forms of arthritis are made possible because of an existing sulfur deficiency. This assumption is most untenable, because the available data must be interpreted as meaning that a sulfur deficiency does not exist.

Forbes and Neale,¹² having demonstrated that the intra-articular injection of indole results in a chronic arthritis, and having observed the elimination of indole in the urine of 34 of 35 patients with arthritis (rheumatoid, hypertrophic and mixed arthritis), advocate the administration of sulfur in various types of arthritis. These authors failed to stress the fact that the intra-articular injection of many innocuous agents will produce a chronic arthritis. Their failure to separate the various types of arthritis indicates that the authors are of the opinion that sulfur deficiency, and in consequence failure to detoxicate indole, are of

primary importance in the production of various types of arthritis. The data thus far presented do not warrant such conclusions.

In view of the above-mentioned data, and the carefully controlled metabolic studies of Frberg, Block and Fromer, which have recently been presented in abstract form,²⁶ it must be concluded that the administration of sulfur to patients with rheumatoid arthritis is not based on scientific fact. It has been our purpose to evaluate, as critically possible, results of colloidal sulfur therapy in a small, carefully studied and well-controlled group of patients with unquestioned rheumatoid arthritis.

METHODS OF STUDY

We²⁷ have previously stated that in a chronic disease of unknown etiology, such as rheumatoid arthritis, characterized by spontaneous remissions, it is extremely difficult to evaluate the results of therapy with any degree of certainty unless the studies are rigidly controlled. Because of the marked variations in the course of the disease from case to case, each patient must be made to serve as his own control. If studies pertaining to the evaluation of therapeutic procedures are not conducted in this manner, one is very apt to conclude that the improvement observed is the result of therapy, whereas it may actually represent a natural variation in the course of the disease. Such a controlled study can be made only by choosing patients whose clinical course and variations in sedimentation rate have been known for months or years prior to the institution of a new form of therapy. An adequate follow-up period is most essential so that one can decide as to the permanency of any improvement noted during the period of therapy. In addition to the above precautions, it is extremely important that the patients be kept on the same basic regime before, during and after the administration of the therapy being evaluated. Every available means should be employed in evaluating clinical improvement. We record separately the subjective, objective and laboratory evidence of improvement, the final result being based on all three. This method of recording enables one to establish more accurately what, if any, psychic effect must be taken into account in the final summation. In all fairness to the type of therapy being studied, only patients whose disease state is active and still reversible should be selected. One must also realize that the early and atypical cases are more apt to show remissions than are the more typical cases which have been more or less stationary for a long time. If the administration of a given form of treatment should result regularly in improvement in this latter group, one might have reason

TABLE 1 DATA ON ALL CASES

| Case* | Sex | Age | CHARACTERIZATION OF AILMENT At Onset At Present | Time Before Therapy | Course | Amount of Sodium Given mg | AL Type of Anemia | Effects Subjective | Die of Therapy Subjective | Results | Comments |
|-------|-----|-----|---|---------------------------|--------|--|-------------------------|-----------------------|--|-----------|--|
| 13 | F | 45 | Mild to Moderate | Moderate | 2 yr | Many good and bad periods, influenced by emotional upsets | 320 | 1 urticaria | Less fatigue and pain | No change | Slowly slight subjective improvement, but no objective gain seen. Had an exacerbation 3 months later. |
| 52 | F | 32 | Moderate | Moderate | 15 mo. | Stationary | 320† | 1 urticaria | Less fatigue and pain | No change | Patient remarked that results were not so beneficial with second course. |
| 116 | F | 39 | Moderate | Moderate | 1 yr | Stationary pain most marked in evening | 310 | 1 urticaria | No change | No change | Subjectively improved. No objective change. After 2 yr. later patient had an exacerbation and ing new joint & well as old. |
| 181 | F | 28 | Mild | Mild | 5 yr | Spontaneous remissions and exacerbations, stationary for past 9 months | 320 | 1 urticaria | No change | No change | N change. Often had to go to bed because of arthritis both during and after course of treatment. |
| 188 | M | 47 | Mild | Moderate | 5 yr | Stationary | 370 | 1 urticaria | Joint is more comfortable | No change | N objective gain seen. Patient believed that he was "helped a little." |
| 203 | F | 31 | Extensive | Moderate | 2 yr | Slowly progressive | 160 | 1 urticaria | No change | No change | N objective gain seen. Patient believed that he was "helped a little." |
| 213 | F | 31 | Mild | Moderate | 4 mo. | Steadily progressive | 370 | 1 urticaria | No change | No change | N objective gain seen. Patient believed that he was "helped a little." |
| 225 | F | 53 | Mild | Moderate | 3 yr | Stationary | 360 | 1 urticaria | Stronger better pain | N change | N slight subjective improvement. One day joint became inflamed while under treatment. |
| 229 | F | 49 | Mild | Moderate | 4 yr | Stationary | 370 | 1 urticaria | Pain stronger and had less pain worse during final week of treatment | N change | N slight subjective improvement. One day joint became inflamed while under treatment. |
| 279 | F | 57 | Extensive | Moderate | 1 yr | Stationary | 320 | 1 urticaria | No change | N change | N slight subjective improvement. One day joint became inflamed while under treatment. |
| M. A. | F | 43 | Moderate | Moderate | 2 yr | Steadily progressive | 340 | 1 urticaria | Better, less second person, much stronger | No change | N slight subjective improvement. One day joint became inflamed while under treatment. |
| D. Z. | F | 45 | Mild | Mild | 2 yr | Stationary | 350 | 1 urticaria | Slight improvement, mainly in evening | N change | N slight subjective improvement. One day joint became inflamed while under treatment. |
| 313† | M | 55 | Extensive | Moderate | 4 mo. | Progressive | 1080 | 1 urticaria | No change | N change | N slight subjective improvement. One day joint became inflamed while under treatment. |
| O. L. | M | 57 | Moderate | Moderate | 1 yr | Stationary | 2580 | 1 urticaria | No change | No change | N slight subjective improvement. One day joint became inflamed while under treatment. |

*Case numbers refer to patients with rheumatoid arthritis who have been studied in detail in the book and will be used in all subsequent publications. Cases listed by initials are patients of one of us (W. B.)

†Second course of treatment.

‡This patient had been given 80 mg previous to this course.

§Includes complete remissions. Present attack of 2 yr. duration.

Treatment of 1160 mg given followed by rest period of 1 mo., then total of 1900 mg. administered.

to suspect that one was dealing with a specific form of therapy

In the present series of patients, all but 2 had been observed for periods varying from one to five years before sulfur therapy was instituted. The two exceptions (Cases 213 and 353) had been on an established basic regime for months prior to hospitalization, without obtaining any appreciable effect. The same basic regime of a high-vitamin, high-caloric diet, added vitamins in the form of cod-liver oil and yeast, daily physiotherapy and constant rations of acetylsalicylic acid, allowed during the pretreatment period, was continued during the sulfur therapy and post-treatment periods.

Fourteen patients—12 ambulatory and 2 hospitalized—were studied. Two of these (Cases 13 and B Z) received two series of injections. Colloidal sulfur in the form of Sulisocol* was given intravenously to 12 patients (fourteen courses) and intramuscularly to 2. Ten patients received a total of 310 to 370 mg of colloidal sulfur over a period of six to eight weeks. One patient became discouraged and discontinued treatment after 160 mg had been given. In order to establish that larger doses (1000 mg or more) were no more efficacious than the previously mentioned smaller ones, 3 patients were given 1080, 1200 and 2980 mg respectively. Twenty milligrams was administered as an initial dose, except for 2 of the patients receiving the larger doses, who received 30 mg initially. Subsequent injections of 30 mg each were given to all patients except those receiving the larger doses. In the latter cases 50 mg was given as a second dose and 100 mg subsequently.

RESULTS

The results of sulfur therapy, as well as a brief clinical résumé of each patient's history, are contained in Table 1. In no case were any toxic symptoms observed. In an occasional case the solution being injected escaped into the subcutaneous tissue, with resultant burning and redness, which subsided quickly with the application of hot dressings. Sloughing of the skin was never observed. In 2 cases a brownish pigment appeared over the dorsum and the palmar surface of the hands. This may have represented a manifestation of the disease.

Subjective improvement, consisting of increased strength and less joint pain, was noted after eight (50 per cent) of the sixteen courses of treatment in the 14 patients. No patient, however, improved objectively. Of the patients subjectively improved, 1 (Case 52) experienced an exacerbation as the course of therapy was being completed. In 1 case

(Case 229) the effect was probably largely psychic, in that improvement was always noted within thirty minutes after receiving the injection and lasted only twelve to forty-eight hours. During the last week of therapy, this patient suffered from a severe exacerbation of her arthritis, involving new as well as previously affected joints. In only 1 case (Case M A) did the subjective improvement last longer than three months. Two patients who improved subjectively following the first series of injections soon experienced exacerbations. In one of these (Case B Z) there was no improvement, in the other (Case 13) the patient improved only slightly with an additional course of therapy.

It has long been our opinion that the corrected sedimentation rate²⁸ is the most reliable single test for determining the activity of rheumatoid arthritis²⁹. When performed at regular intervals, it can often be relied on to measure more accurately the activity of the disease than does the physical examination. As can be seen from Table 2, this test

TABLE 2 Sedimentation Rates Observed in Patients Receiving Colloidal Sulfur

| CASE | CONTROL PERIOD* | | | IMMEDIATELY AFTER TREATMENT | FOLLOW UP RATES | | | |
|--------------------|-----------------|------|------|-----------------------------|-----------------|------|------|------|
| | HIGH | LOW | LAST | | 1 MO | 2 MO | 3 MO | 6 MO |
| | mm | mm | mm | mm | mm | mm | mm | mm |

| 225 | 1.13 | 0.90 | 1.13 | 0.92 | 1.16 | — | — | 0.94 |
| 229 | 0.70 | 0.68 | 0.70 | 1.12 | 0.84 | 0.71 | 0.59 | 0.6 |
| 353 | 0.72 | 0.71 | 0.72 | 0.94 | 0.92 | 0.83 | 0.73 | 0.74 |
| M A | 1.52 | 0.95 | 1.52 | 0.97 | — | — | 1.02 | 0.79 |

*Sedimentation rates for the control periods represent the variations for the preceding six months except for Cases 188 and 213 in which the rates cover only two months and Cases 225 and 353 one month. The rates are expressed in millimeters per minute the upper limit of normal being 0.40

was performed at regular intervals before, during and after therapy in 10 cases receiving eleven courses. We used the same criteria for judging improvement, as measured by the sedimentation rate, previously described²⁷. A drop of 0.15 mm per second was considered significant when the initial rate varied from 0.5 to 1.0 mm per minute. A drop of 0.2 mm per second was judged significant if the initial rate varied from 1.0 to 1.5 mm per minute, whereas a drop of 0.3 mm per second was considered significant if the initial rate exceeded 1.5 mm per minute.

Employing these criteria, only 3 patients (Cases 188, 225 and M A), showed significant drops in the sedimentation rate. In 2 of these (Cases 225 and M A) the decreased rate accompanied subjective improvement. In the third, the rate re-

*Supplied through the courtesy of Drug Products Company Incorporated Long Island New York

turned to the pretreatment level one month after therapy was completed. The lowered rates in Cases 225 and M A were maintained for twelve and eighteen months, respectively, despite the fact that objective improvement was not noted. In no case did the sedimentation rate return to normal.

Discussion

From the above results it seems reasonable to conclude that colloidal sulfur, even when administered in large doses, does not alter the course of rheumatoid arthritis. While the number of cases so treated is small, the uniformity of the results renders them significant.

It will be of interest to those workers who have contended that a primary sulfur disturbance exists in patients with rheumatoid arthritis to learn of the results obtained by Freyberg, Block and Fromer¹⁶ in carefully executed metabolic experiments carried out on patients with rheumatoid arthritis and on control subjects. Their results show that there exists no fundamental difference in the amount of sulfur excreted or the manner in which it is excreted by arthritics and by control subjects.

The injection of colloidal sulfur affected the metabolism and excretion of sulfur in patients with rheumatoid arthritis in the same way as it did in normal individuals. When injected intravenously the sulfur excretion in all but one patient increased by amounts considerably greater than the amount of sulfur injected. Thus the injection of colloidal sulfur actually created a deficiency of sulfur. Obviously then, this method of treatment could not be expected to prevent or diminish a deficiency of sulfur in the body if such deficiency existed. Injected sulfur was eliminated chiefly as inorganic sulfate; there was no important increase in the conjugation of sulfur and hence no benefit could result by conjugation of toxic substances. Sulfur given orally in colloidal form and as sodium thiosulfate effected the same changes in the arthritics as in the normal individuals; there was no increase in conjugation of sulfur. Thymol was readily conjugated with sulfuric acid by the arthritic patients and the controls similarly, thus indicating no impairment of this detoxifying mechanism and no need for sulfur medication on this account. Our analysis of fingernails showed no changes in the cystine content after sulfur medication.

These same authors conclude

No evidence of sulfur deficiency or abnormality in sulfur metabolism was found to exist in patients with rheumatoid arthritis. The data of this study reveal no biochemical or metabolic indication of need for or benefit from sulfur medication in the treatment of rheumatoid arthritis.

From the above, it appears that the physician who fails to administer colloidal sulfur to a patient with rheumatoid arthritis is not guilty of neglect. Colloidal sulfur therapy represents another anti-rheumatic remedy which can be dispensed with in the treatment of rheumatoid arthritis, with con-

siderable saving of expense to the patient. Milder toxic reactions have been observed. One must further realize that the administration of any therapy intravenously is not without danger.

The data contained herein are in agreement with the action taken by the Council on Pharmacy and Chemistry of the American Medical Association,¹⁷ which has been unwilling to include in its list of approved new and non-official remedies any of the colloidal sulfur preparations now on the market. The Council stated that such a product was not acceptable because of the lack of evidence of its therapeutic value.

SUMMARY

Evidence is cited which proves that a primary disturbance of sulfur metabolism does not exist in patients with rheumatoid arthritis.

Data are presented showing that the administration of colloidal sulfur in small or large doses does not alter the course of rheumatoid arthritis, as measured by objective or laboratory evidence of improvement in well-controlled cases.

REPORT ON MEDICAL PROGRESS

SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM, WITH PARTICULAR REFERENCE TO VASCULAR DISEASE

REGINALD H SMITHWICK, M D *

BOSTON

INTERRUPTION of sympathetic pathways in man is extremely helpful in the treatment of many disorders, particularly those involving the vascular system. This field is a very open one, especially as far as etiologic factors are concerned. In many disorders amenable to treatment by sympathectomy, the question may be raised as to whether they are due to disease of the arteries themselves, or whether increased sympathetic outflow actually exists, and in turn results in diminished blood flow to the part, and later in pathologic changes in the arteries. In other words, is one dealing with primary vascular disease or with a lesion of neurogenic origin? In this connection one might refer to the long-standing disagreement concerning the etiology of Raynaud's disease. Much of the evidence available on this matter may be utilized in support of either viewpoint. The difficulty is that no conclusive data exist, because most methods of study involve a measurement of the sum total effect of vascular disease and sympathetic influence. The matter can be settled only by separating the two, and by demonstrating conclusively that increased sympathetic motor impulses either are or are not present. There is a tendency, by those who favor the vascular theory of origin, to conclude or imply that sympathectomy is therefore not indicated as a form of treatment. This often applies to their attitude toward the indications for sympathectomy for vascular disease in general. They appear to hold that because a disease may not be neurogenic in origin, interruption of sympathetic pathways is illogical. In the matter under discussion, Sir Thomas Lewis,¹⁻³ the most steadfast and devout exponent of the "local fault" theory, believes nevertheless that sympathectomy, particularly the preganglionic

type, is the treatment of choice for this disorder. All who are familiar with the benefit which follows a properly executed sympathectomy will agree.

The effect of extensive sympathectomy in animals is always a source of interest, and yields information that may be of help in the understanding of disease in man. One must be cautious, however, in the interest of the patient, in concluding that the effect of sympathectomy on normal animals will be the same in human subjects with disease. Conversely, one must not be too hasty in assuming that the effect of sympathectomy in animals with induced disease, not identical with that found in man, will necessarily be duplicated in the latter. Particularly dangerous is a tendency by some to work out anatomic pathways in man by inferences drawn from animal investigation.

One always turns with interest to the report by Cannon and his co-workers of their experience with ablation of sympathetic influence in animals. Of particular interest is the striking difference in the effect of total sympathectomy in the cat and in the dog. This matter has recently been discussed in a series of articles⁴⁻⁸ showing that a cat devoid of its sympathetic nervous system is extremely sensitive to heat and cold, to anoxemia, to blood loss and particularly to muscular exercise. A dog, on the other hand, responds in an almost normal manner under these same conditions. Both cats and dogs are alike in being extremely sensitive to insulin after sympathectomy.

These findings serve to emphasize the danger of drawing conclusions by inference, even among animals of different species. It would appear even more questionable to conclude what the effect of sympathectomy would be in man from experimental work carried out in animals. Most authorities agree that the effect of elimination of

*Instructor in surgery Harvard Medical School assistant visiting surgeon Massachusetts General Hospital

sympathetic influence in man had best be determined by a careful study of the end results of various procedures as applied to man, rather than by inference from animal experimentation

The technic of sympathectomy, as related to the extremities, in man is now well standardized. As a result of many years of trial and error, operations have been devised to fulfill certain necessary qualifications. These have been set up and determined by a close comparison of the end results of different procedures. Sympathectomy is followed by the best clinical results when the area in question is thoroughly denervated, by preganglionic rather than postganglionic section. Care must be taken to guard against regeneration of interrupted pathways, in order that the late results may not suffer by comparison with the satisfactory immediate effects. Reference is made to the technic that best fulfills these qualifications.⁷ While to perform these operations requires specialized knowledge and training, they carry a minimal risk to the patient, short periods of disability and no serious untoward effects. Preoperative studies make it possible to predict the result to be expected with a high degree of accuracy. Clinical experience is also important in this regard.

CIRCULATORY DISORDERS OF THE EXTREMITIES

Particularly useful is sympathetic denervation of the extremities for circulatory disorders. These may be chiefly vasospastic in nature (Raynaud's disease), with undemonstrable to moderate or organic changes in the arterioles. The earlier sympathectomy is performed, the better the result. In such cases, spasm in response to cold, pain and emotion is virtually eliminated, blood flow is greatly increased and the symptomatic relief is impressive. When local tissue damage already exists, the operation results in increased tolerance to cold and shorter, less intense periods of vasoconstriction. Similar relief follows sympathectomy for vascular spasm secondary to underlying disease such as anterior poliomyelitis, thromboangiitis obliterans and certain of the causalgias. The cold, blue, cyanotic extremity with chronic or persistent ulceration that sometimes follows infantile paralysis may be rendered warm, dry and pink by sympathectomy. In young children where a discrepancy in the rate of growth of the two extremities exists, sympathectomy may be utilized to decrease the eventual difference in the length of the two limbs. As an adjunct to the treatment of thromboangiitis obliterans, the value of sympathectomy should not be underestimated. It has been a highly significant factor in the reduction of the incidence of major amputations in this disease, from approx-

mately 75 per cent fifteen years ago to 6 per cent at the present time.

Under the diagnosis of causalgia, certain patients are grouped who suffer from painful lesions of the digits or extremities resulting from old injuries or infections. The extremity is cold, cyanotic and extremely sensitive. A tender, scarred amputation stump may be present. If temporary relief of pain with improved circulation follows paravertebral novocain block, sympathectomy has been found to be extremely valuable in the rehabilitation of such patients. If the local fault is great, reamputation may also be necessary. The latter is not successful as a rule, unless the circulation is first restored by sympathetic denervation.

The importance of reflex vascular spasm as associated with sudden occlusion of peripheral arteries should be emphasized. This applies particularly to embolic occlusion and also to sudden thrombosis. The entire peripheral vascular tree constricts reflexly under these circumstances. This hinders the development of collateral circulation, and is a vital factor in the high incidence of major amputations after occlusion of large arteries such as the femoral. A similar mechanism is present following injuries of main arteries by laceration and gunshot wounds. In the upper extremity, occlusion of the brachial artery may be related to cervical ribs, anomalous first ribs and the scalenus anticus syndrome. More recently, the importance of reflex vascular spasm and its relation to acute thrombophlebitis of femoral and iliac veins have been stressed by Ochsner and DeBakey.⁸ In all the above conditions this reflex may be abolished by repeated paravertebral novocain block by paravertebral alcohol injection or by sympathectomy when feasible and necessary.

The gratifying relief afforded by sympathectomy to those who suffer from extreme and uncontrolled perspiration of the extremities (hyperhidrosis) has been re-emphasized by White.⁹ In this disease, excessive activity of the sweat glands is presumably neurogenic in origin. Increased vasoconstriction does not necessarily accompany the increased sudomotor activity. Because sympathectomy is followed by complete abolition of sudomotor reflexes, the clinical result is impressive. The hands or feet are rendered dry and warm.

HYPERTENSION

This very important manifestation of disease is one of the most discussed problems in medicine today. It is well that this is the case for there are few matters of greater consequence to man. The cause of high blood pressure in a certain group of patients who are classified as suffering from

essential hypertension is still unknown. That high blood pressure may result from intracranial lesions, from arteriosclerosis, from tumors of endocrine glands, more particularly the basophilic adenoma of the pituitary and the medullary adrenal neoplasms, and from renal disease, polycystic kidneys, embryomas and pyelonephritis, as well as from other causes, is well known.

It is obviously highly desirable that a patient with hypertension be studied in a detailed manner and that all possible known causes of hypertension be excluded. The brilliant researches of Goldblatt, Kahn and Hanzel¹⁰ have served to focus attention on the kidney, and as a result a certain group of patients can be segregated who will benefit by the correction of renal disease. As yet there are few such examples on record, but others will appear in time. It would seem, however, that there will still remain a large group of cases in which no cause for hypertension can be found.

In a study of 212 patients who presented themselves for treatment because of hypertension, Palmer¹¹ found evidence of marked renal disease (asymptomatic) in 47 as a result of routine intravenous pyelograms. In 33 cases the disease was unilateral. The affected kidney was removed in 9 of these cases. The blood pressure was favorably affected in 1, and possibly reduced in 2. Palmer expresses the opinion, which is also held by others, that nephrectomy in cases with unilateral renal disease in order to be effective in lowering blood pressure must be done in young patients in whom the renal disease is of very recent origin.

In essential hypertension no renal disease can be demonstrated in the early stages. It is conceivable, however, that some abnormality of the renal circulation, undemonstrable by modern methods of study, may be present. The arterioles may be constricted by some intrinsic or vasomotor mechanism. This might result in elevation of blood pressure, and in turn in generalized arteriolar constriction as a protective mechanism to prevent damage to tissues. Many authorities hold the viewpoint that high blood pressure is caused by a generalized constriction of arterioles due to vascular disease. Under these circumstances, high blood pressure is the compensatory mechanism for assuring adequate tissue nutrition by forcing sufficient blood through the constricted arterioles. All agree that in this condition the peripheral resistance to blood flow is increased.

Whatever may be the true explanation, the purpose of sympathectomy is to eliminate vasoconstriction where it is most likely to affect the general blood-pressure levels. Vasoconstriction in certain portions of the vascular bed has a much

greater effect on the general blood pressure level than it has in others. For instance, peripheral vasoconstriction has little effect on blood-pressure levels as contrasted with splanchnic constriction. What portion of the splanchnic bed is most important is a question, but one may suspect the renal vascular bed to be particularly so.

One knows from experience with peripheral vessels that vascular relaxation with increased blood flow to the part may occur and persist after sympathectomy, whether the vessel be normal or constricted. The latter may be due to intrinsic disease or increased vasomotor activity, or to a combination of both. In experimental hypertension in animals induced by renal ischemia, a chemical factor, renin, elaborated by the kidney appears to cause the hypertension. That this is also true in man is not as yet known. In animals, this chemical factor disappears if the constricting band is removed before irreparable damage has been done to the kidney. How often a corresponding renal ischemia is the cause of continued arterial hypertension in man is unknown. Nor is it certain whether the original vascular constriction is functional and reversible or organic and irreversible, or whether both factors play a part.

The purpose of sympathectomy is to denervate the blood vessels of the splanchnic bed. Included in this are the kidneys and the adrenal glands. It is essential that the latter be denervated because all sympathectomized vessels will constrict in response to increased secretion of adrenaline into the blood stream. In order that the relaxation be as complete as possible, it is therefore necessary to abolish reflex secretion of adrenaline. Furthermore, the action of adrenaline and similar hormones on denervated arterioles is greater after postganglionic section. It appears wise, therefore, to perform a preganglionic type of denervation so far as possible.

Several methods of splanchnic denervation are in use today. A detailed report of the effect of supradiaphragmatic splanchnic resection (Peet) on hypertensive patients has been made by Braden and Kahn.¹² In a careful review of 264 cases followed for six months to five years, they report an operative mortality of 3 per cent and find that 23 per cent of patients have died since operation. In the remaining cases they find significant reduction of blood pressure in 43 per cent. Of those who were incapacitated before operation, 84 per cent were able to return to their former activities. Symptomatic relief was obtained in 87 per cent. Changes in eyegrounds, as well as in cardiac and renal function, are discussed in some detail.

Adson,¹³ in discussing his experience with subdiaphragmatic splanchnic resection, stresses the importance of the selection of cases. He believes

that the response to sedation and to stimulation by the cold pressor test are valuable guides. In an unselected group of 156 cases, there was 1 operative death. Normal blood pressures resulted in 20 per cent of cases, and significant lowering in 35 per cent. Symptomatic relief in these two groups ranged between 85 and 95 per cent. No effect on blood pressure was noted in 20 per cent, and temporary lowering (six months to two and a half years) was noted in 25 per cent. Adson believes that better results will be obtained in carefully selected cases.

Davis and Barker¹⁴ found that 4 patients who were resistant to sulfocyanate therapy before operation responded favorably to this drug after bilateral supradiaphragmatic splanchnic resection had failed to influence the blood pressure levels. In dogs made hypertensive by renal ischemia (Goldblatt), the blood pressure fell in every case in response to sulfocyanate. This was accompanied by a fall in hematocrit, total protein, urea nitrogen and cholesterol similar to that seen in man. These authors are as yet unable to state whether the response to sulfocyanate in Goldblatt dogs which have also had bilateral supradiaphragmatic splanchnic resection is more marked than in unsympathetized dogs. They have not found a Goldblatt dog that was resistant to sulfocyanate.

My own experience with supradiaphragmatic and infradiaphragmatic resection is similar to that reported by Peet and Adson. I have noted however, that in favorable cases in the same stage of the disease the effect of operation on blood pressure is not always uniform. In fact, there may occasionally be no demonstrable change in blood pressure after operation in patients who do not have sufficient organic vascular disease to account for such a result. It appeared reasonable to suspect that this might be due to incomplete splanchnic denervation because of anatomic variations. For several years I have been varying my operative technique so as to find the minimal procedure that would give good evidence of having resulted in adequate splanchnic denervation. The production of a postural fall in blood pressure has been used as an index of the completeness of interruption of sympathetic pathways. It appears that in order to produce this change in every case, the entire great splanchnic nerve must be removed with its branches to the aorta above the diaphragm and the sympathetic trunk must be removed from above the ninth dorsal to below the first lumbar segment. This requires exposure both above and below the diaphragm which is obtained by resecting the twelfth rib. It enables one to inspect the kidneys and adrenal glands as well. The early effect of this procedure in a small group of cases

operated on during the past year has recently been reported.¹⁵

It would appear that adequate splanchnic denervation in selected cases will result in material and persistent lowering of the blood pressure levels. The true value of sympathectomy as a form of treatment of essential hypertension in man will not be known for several years.

BLADDER PAIN

The relative importance of afferent sympathetic, somatic and parasympathetic pathways from the bladder has been discussed in some detail by Schroeder¹⁶ and Nesbit and McLellan.¹⁷ Both find that resection of the presacral nerve may be very helpful in alleviating the discomfort associated with tuberculosis and interstitial cystitis. The former believes that extirpation of the lateral sympathetic chains as well gives even greater relief, but that intraspinal alcohol injection also may occasionally be necessary. Nesbit and McLellan, on the other hand, find presacral neurectomy alone as effective as if combined with removal of the lateral sacral sympathetic chains. They further believe that few if any pain pathways are interrupted, but that the relief of pain is due to relaxation of the internal sphincter, with elimination of the intense spasm of this muscle which is associated with micturition. In other words, they believe that relief is due to interruption of motor rather than sensory pathways.

ANGINA PECTORIS

The problem of intractable angina and what can be done to relieve it is still under discussion. There are three approaches to be considered: interruption of sympathetic sensory and motor nerves to the heart, lowering of the metabolic needs by total thyroidectomy and increase of the collateral circulation of the heart. The cardiac nerve supply may be interrupted either by actual division or by paravertebral alcohol injection of the nerves concerned.¹⁸ While the former would give a higher percentage of excellent results in those who survived, one must be willing to accept an operative mortality of at least 15 per cent and perhaps higher. Paravertebral alcohol injection results in relief in about 80 per cent of cases, with a mortality of between 1 and 2 per cent. It has therefore taken the place of more risky operative intervention. Raney¹⁹ has recently advocated division of the communicating rami of the second to the fifth dorsal segments, inclusive. He reports a small series of cases with excellent results and without mortality. Exactly the same pathways are interrupted by alcohol injection, and the lat

ter will always carry a much lower mortality. The fact that Raney attributes the benefit to section of motor rather than sensory pathways is more of academic than of practical significance. Moreover, ramisection has never been found to stand the test of time, because of regeneration of interrupted pathways. Alcohol injection lasts as a rule for several years, and can be repeated. Reoperation is not practical. Besides relief of pain, alcohol injection may also result in increased cardiac reserve.

Total thyroidectomy²⁰ is to be considered in a small group of carefully selected cases. It does not have the universal applicability of alcohol injection. The mortality, however, is low (about 4 per cent). The procedure has untoward side effects, myxedema in particular. It does not increase blood flow to the heart, but decreases the demands on the cardiac circulation.

Attempts to increase the collateral circulation of the heart in order to relieve angina may be viewed with interest. By this method, it would appear that if successful one has a chance of prolonging life expectancy. However, the operations (Beck,²¹ Davies, Mansell and O'Shaughnessy²²) are of great magnitude, and carry a high mortality. Those who survive appear to obtain decided benefit. Sufficient time to evaluate this procedure has not elapsed.

At present, it appears that paravertebral alcohol injection is the treatment of choice, and most surgeons would select this method for themselves.

CASE 26131

PRESENTATION OF CASE

A thirty-four-year-old man was admitted to the hospital complaining of hematuria.

The patient was apparently well until the morning of the second day before admission when he suddenly developed a crampy, moderately severe, non-radiating pain in the right lower quadrant of the abdomen. The pain persisted for five minutes, passed away and recurred in the afternoon, although at this time it was less severe. It disappeared after a heavy evening meal, and because of this, the patient thought that the discomfort was a "hunger pain." He was awakened from a sound sleep by another episode of the right lower quadrant pain, but it lasted only a few minutes, vanishing after drinking water. He returned to sleep, awoke at his usual hour, and passed urine intimately mixed with bright red blood. A second specimen passed a few hours later was also bloody. He then came to the hospital and was admitted. The family, marital and past histories were non-contributory.

Physical examination revealed a well-developed and well-nourished, moderately pale man in no apparent discomfort. There was "moderate tenderness along the course of the right ureter and in the right lower quadrant with voluntary spasm." The remainder of the examination was negative.

The temperature, pulse, respirations and blood pressure were normal.

Examination of the blood showed a red-cell count of 5,110,000 with 90 per cent hemoglobin. The urine was bloody and acid in reaction with a specific gravity of 1.014 and a ++++ albumin test; the smear showed no organisms but many red blood cells.

At cystoscopy, the instrument passed easily. The bladder was evacuated of a moderate amount of bloody urine. The bladder mucosa was normally pale. No stones, tumors, ulcers, diverticula or other abnormalities were noted. The ureteral orifices were normal. Clear urine was seen to spurt from the left ureter, bloody urine from the right. The right ureter was easily catheterized.

A flat plate of the abdomen was negative except for slight scoliosis of the lumbar spine toward the right. No stones were seen. By intravenous pyel-

ograms the dye was excreted promptly from both kidneys, outlining normal pelvis and calyces on the left. On the right side the calyces were normal in appearance, but the pelvis was slightly larger than the one on the left; there was no appreciable dilatation, however. Retrograde pyelographic filling showed non-dilated kidney pelvis on the right, the two uppermost calyces showed unusually large pyramids, and there was slight fuzziness of the uppermost calyx.

He continued to pass bloody urine. On the day after admission an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. SALVESTER B. KELLEY: The urologist takes blood cells in the urine very seriously. It has been my suspicion that my medical conferees consider microscopic blood in the urine somewhat lightly, assuming that a man may have inflammation of the urinary tract or a mild nephritis. But urologists believe that hematuria is still the best indication of tumor along the urinary tract, of stone, of tuberculosis or of an inflammatory reaction in the bladder or prostate. This man apparently had been well until two days before admission. The sudden disappearance of pain is unusual in a case with a stone in the urinary tract. The fact that the pain passed away suggests it may have been due to a blood clot that caused temporary obstruction as it was descending through the narrow portions of the ureter. I cannot account for the disappearance of pain after the heavy evening meal. It seems to me a coincidence rather than a factor of any significance in his discomfort.

"He was awakened from a sound sleep by another episode of right lower-quadrant pain. That suggests another clot from the kidney during the night. When he awoke he passed urine intimately mixed with bright red blood. I think the word 'intimately' is an excellent description. It helps the urologist a great deal to know whether the blood is mixed with the whole quantity of urine or whether the bleeding is initial or terminal. Initial hematuria frequently is associated with inflammatory conditions of the prostate. But with clear urine at the beginning of micturition, and a few drops of blood at the end of the stream, we think of a pathologic lesion in the bladder—an acute inflammatory reaction or papilloma. As the bladder contracts it squeezes the lesion and causes it to bleed."

It is of some significance that the family and past histories were negative. When I have a patient with hematuria and pain in the side I go into the history in detail. Very frequently, for example, I find in patients with urinary calculi that

there has been an excessive ingestion of food containing large amounts of calcium, such as milk and cheese. Most recently I have seen a girl who took on her own responsibility a large amount of calcium for some dermatologic condition, and who subsequently developed a stone in the kidney.

The physical examination is helpful in that it reveals a well-developed individual in no apparent distress. The development suggests that he had no tuberculosis. The patient with hematuria frequently looks rather washed out. One often thinks of kidney tumor as presenting the symptoms of pain, a mass in the upper quadrant and hematuria, it should be pointed out, however, that pain is a relatively late manifestation, being the result of necrosis or infection. I am a little skeptical of the observation that the pain followed the course of the ureter. Many attacks of renal colic are associated with pain, localized in the right lower quadrant at a spot which Dr J D Barney once described. If one draws a line between the anterior superior spine of the ilium to the umbilicus, bisects it and then goes downward at a right angle for 25 cm one comes to Barney's point.

The blood pressure was normal, and this, taken with the rest of the picture, makes us fairly sure there was no medical cause for the hematuria, such as nephritis. The red-blood-cell count was normal. I think the ++++ albumin test is a little misleading and undoubtedly due to the large amount of blood in the urine.

Cystoscopy revealed very little. It is quite significant, however, that clear urine was seen to spurt from the left and blood from the right ureter. That is the great advantage of doing a cystoscopy at the time of bleeding. Catheterization is of some significance. While it sometimes is possible to slip a catheter past a ureteral stone, the latter usually obstructs the passage of an instrument from below.

The fact that no stone was seen in the plain x-ray film helps a little. In such a plate one frequently overlooks calculi which are composed of uric acid or which lie in front of the pelvis or spine, therefore a flat plate is not necessarily conclusive. The intravenous pyelogram indicated good function on the right side, but a slightly dilated pelvis. I should attribute this dilatation to blood clot in the kidney pelvis.

I attach great importance to the fact that there was slight fuzziness in the upper calyx. That suggests a tumor growing from the calyx down toward the pelvis. If it had been due to tuberculosis one would not find fuzziness but probably a dilatation of the calyx.

The man continued to pass blood, and an oper-

ation was performed. He was rather young for a renal tumor to occur, the majority of them coming between forty and fifty. There is no evidence of tuberculosis either in the history or physical findings, and I do not believe there was a stone because there was no evidence of obstruction of the ureter and subsequent dilatation. There is no evidence of nephritis from the x-ray description. I should say that this man had a carcinoma originating in the upper calyces of the kidney.

Dr Holmes may offer some suggestion.

DR GEORGE W HOLMES. I hope I may help you a little. Here is the defect described, if one may call it defect. Apparently the upper calyx is one of these bifid affairs with a long narrow infundibulum. The portion connecting it with the pelvis is definitely narrowed and constricted. Usually we should expect another calyx in this region, but there is no indication of it here, not even irregularity in outline. I am not justified in saying that there is a blocked-off calyx. It might be an anatomic variation. The ureter is well filled, with no sign of dilatation or obstruction. In the plain film there is nothing to suggest stone, and the kidneys are normal in size. I should like to take issue with Dr Kelley on his statement about stones. It is true that radiologists overlook them, but their shadows are usually in the films and can be seen if looked for carefully. Dr H O Petersen reviewed 100 cases from the hospital not long ago. While it is true that negative reports were made where stones were present in a considerable number of cases, on re-examination, knowing that there were stones, he was able to find them in all but 2 cases.

Dr Kelley. I stand corrected.

Dr TRACY B MALLORY. Dr Smith, you might tell us your impressions and findings.

DR GEORGE G SMITH. I operated on this man because I believed that the definite scallop in the outline of the upper border of the pelvis was significant of a pressure defect, and because of the apparent slight dilatation and a filling defect in the upper calyx, together with a hematuria. I was not at all sure that he had a tumor of the kidney but believed that there was a strong probability and that it would be much better to explore him and, if I found an early tumor, take the kidney out, than it would be to wait until the diagnosis was absolutely certain. So I operated on him with a diagnosis of probable tumor of the kidney.

At operation a fairly normal looking kidney came into view except that on the anterior surface there was a cyst which extended from the hilus to the periphery. It was about 25 cm wide and apparently occupied the entire parenchyma on that side. I was uncertain for the moment whether that explained the whole thing and whether it

would be better to leave the kidney in, but on palpating the kidney carefully I felt a very hard area buried in the parenchyma just above the hilus and just below the cyst. That was difficult to explain, but it was suggestive enough of tumor so that I removed the kidney.

CLINICAL DIAGNOSIS

Right renal calculus?
Renal cyst?
Renal tumor?

DR. KELLEY'S DIAGNOSIS

Papilloma of right kidney pelvis.

ANATOMICAL DIAGNOSIS

Tuberculosis of kidney

PATHOLOGICAL DISCUSSION

DR. MALLORY The kidney presented a rather unusual appearance. When it was sectioned we found two spherical, slightly white nodules that seemed rather fibrous in character, neither of them particularly suggestive of tumor, nor did either of them show obvious caseation. With a little more exploration a third nodule was discovered at the upper pole of the kidney, and this was frankly caseous in the center. On microscopical examination all three nodules proved to be tuberculous, and there was slight tuberculous erosion of the tips of a couple of pyramids, but the major lesion consisted of these three circumscribed solitary tubercles, which grossly had the appearance of tumor.

DR. HOLMES It is not surprising under the circumstances that the pyelogram was very misleading. I cannot remember ever having seen renal tuberculosis in this region.

CASE 26132

PRESENTATION OF CASE

A fifty-year-old Russian housewife was admitted complaining of abdominal pain.

One week before entry, following a banquet, the patient experienced a sensation of mid-epigastric fullness, which radiated around both costal margins to the back. Removal of her corset afforded considerable relief and, except for malaise, the patient felt well during the next two days. Four days prior to admission she was awakened in the morning with dull aching pain along the lower rib margins on both sides, radiating to the right shoulder blade. She was unable to put on her corset because of tenderness in the right upper abdomen. The tenderness became exquisite, and two days before coming to the hospital the patient noted a lump in the right upper quadrant.

There was no nausea, vomiting or colicky pain. Bowel movements, which had always occurred regularly daily, became costive during the week of illness. The upper abdominal pain persisted until entry.

The past history was noncontributory.

Physical examination showed a well-developed and nourished woman lying comfortably in bed. The lungs were clear. The heart was not enlarged, but a soft blowing systolic murmur was heard in the third left interspace. The blood pressure was 175 systolic, 100 diastolic. The abdomen was soft, but there was slight tenderness in the right upper quadrant. A smooth mass, evidently liver, with a sharp edge, extended four fingerbreadths beneath the costal margin from the epigastrium laterally into the right flank. Attached to it in the midclavicular line was a prominent, firm, walnut-sized knob. The remainder of the examination was negative.

The temperature, pulse and respirations were normal.

Examination of the urine showed a specific gravity of 1.030, with a slight trace of albumin, a green precipitate was produced by Benedict's test, and the sediment was negative. The blood showed a hemoglobin of 90 per cent and a white-cell count of 10,150. The nonprotein nitrogen of the blood was 26 mg per 100 cc. The blood sugar was 246 mg per 100 cc, and the carbon-dioxide combining power 55.3 vol. per cent.

A plain x-ray film of the abdomen showed an ovoid mass of calcification just above the hepatic flexure of the colon. The mass measured 5 by 3.5 cm and was not homogeneous, the denser portion being in its center. A Graham test showed no filling of the gall bladder. With the patient standing, the area of calcification changed its shape and exhibited a definite fluid level, 4.5 cm in width, the denser portion of the shadow was there in the lower part of the mass.

Two days after entry a laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. WALLACE This fifty-year-old housewife had been quite well until one week before admission, when she had mid-epigastric fullness which radiated around both costal margins to the back. This episode suggests the onset of gallstone symptoms, without, on this first attack, residual symptoms to indicate complicating inflammation. However, recurrence of pain in this region, radiating to the back with increasing severity and persistence of tenderness and pain for four days are strongly suggestive of obstruction of the cystic duct and inflammation of the gall bladder. We must, however, consider subacute perforation of a peptic ulcer and perihepatitis. Cirrhosis is

possible, but congested liver unlikely without other positive findings of heart failure

Incidentally, mistaking perihepatitis for acute cholecystitis is a fairly common error, but usually occurs in cases in which there is more tenderness and spasm and the gall bladder is not felt. In this case the palpation of a mass below the liver edge is good confirmatory evidence of cholecystitis.

The blood sugar is not reported as a fasting specimen but even so the patient must have been diabetic. Since the pancreas is under suspicion we should mention pancreatic duct stone and pancreatitis, but there is no record of tenderness posteriorly to support either diagnosis. I do not believe diabetes plays an important part in her illness, but gallstones and acute cholecystitis are commoner in diabetics than in non-diabetics. The normal temperature and pulse and the white count of 10,000 with a four-day story probably mean that the gall bladder was not really acutely inflamed, but they are quite consistent with cystic duct blockage and a tense edematous gall bladder. However it is frequently difficult to correlate the acute or subacute gall bladder found at operation with the history, physical examination and laboratory data. There is no mention of jaundice, and the single attack of persistent pain rather than repeated attacks of colic is against the likelihood of finding a stone of the common duct. In a recent review¹ of the cases of common-duct stone in this hospital, 37 per cent of them were found in the absence of jaundice. In this group the most reliable point in the history was colicky pain recurring every week or at more frequent intervals.

The x-ray films showed a mass of calcification in the right upper quadrant. Presumably there had been no previous examination with barium or other opaque media. A calcified mass in this region might be a calcified hematoma, lymph node, echinococcus cyst or even tumor, and of course might be a gallstone or a kidney stone. I believe we can rule out all these possibilities, however, as they are all solid masses, whereas the films showed change in shape and a fluid level with change of position. The Graham test showed no filling of the gall bladder, and I assume it did not empty with a fatty meal. In addition the denser portion of the shadow shifted to the lower part of the mass. This must mean fluid rich in calcium or other radio-opaque material confined to a sac. I know of only one condition which gives this picture, and this is rarely recognized preoperatively.

The two most recent articles I can find are in the German literature^{2,3}

This case, I believe, had all the essentials of the disease. The first essential is cystic-duct obstruction,

which probably has been present long before the initial symptoms as it is a gradual process. Pain then occurs with the distention of the gall bladder. Finally comes the palpable gall bladder, which is not really tender since acute inflammation is not a part of the picture. The x-ray findings are characteristic, and the important points are just as described—a calcified mass, as seen in a plain film, which, with change of the patient's position, has a change of shape and a definite fluid level with the denser portion of the shadow in the lower part of the mass. If cholesterol or cholesterol calcium stones are present, they float on top of the heavy fluid which is chiefly 85 to 95 per cent calcium carbonate and is called "chalk bile" or "lime-water bile."

The unopened organ should have the appearance of a hydrops of the gall bladder with cystic duct obstruction, and I believe the opened specimen should show no bile but a white liquid composed chiefly of salts of calcium.

PREOPERATIVE DIAGNOSES

Cystic duct stone

Hydrops of gall bladder ("milk-of-calcium bile")

DR WALLACE'S DIAGNOSIS

"Chalk bile" gall bladder

ANATOMICAL DIAGNOSES

Chronic cholecystitis

Cholelithiasis

Hydrops of gall bladder (calcium-milk bile)

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: The distinctly unusual x-ray findings in this case permit, if one knows how to interpret them, a diagnosis of exceptional accuracy, which Dr Wallace has just made. The patient was operated on by Dr Edward L. Young, who found a slightly dilated, thickened gall bladder, which was completely obstructed by two stones in the cystic duct. It was removed without difficulty, and the common duct was explored and found to be negative. On opening the gall bladder a hydrops was found. There was about 50 cc. of colorless fluid which contained a thick sediment of white chalky material. A single small calcium stone 5 mm in diameter was found, and the remaining particles were of microscopic size. The wall of the gall bladder showed definite fibrous thickening and a slight inflammatory reaction.

DIRECTORY OF MEDICAL SPECIALISTS

With the publication of the *Directory of Medical Specialists** there is now available a list of certain practitioners of medicine and surgery who have been judged by their elected representatives to be worthy of isolation from the general mass of their co-practitioners. They have demonstrated to the satisfaction of various examining boards that they have more than usual ability, or if one prefers, a minimal acceptable ability, to practice their chosen specialty and have agreed to limit their practice to that particular field. Such a procedure and such a segregation cannot be commended too highly. It is in line with the other great steps that have been taken in the past by the medical profession for the protection of the public, and particularly supplements the now general recognition of the fact

that hospitals are the best places for sick people, and the increasingly common requirement that hospitals have some sort of closed staff control.

A brief study of the life history of these two latter reforms in medical practice demonstrates at once, however, that neither reached its greatest usefulness until after the public—that is the patients—had been educated. Time and experience had to accumulate before the education took effect. So today, before the full public worth of this latest reform movement within the medical ranks can be attained, time and experience must again accumulate and the public must again be educated up to the point of acceptance.

The truism that anything that is worth doing at all is worth doing well should nevertheless be taken to heart by all originators of reform or educational movements. In particular this applies to the examinations given by the various American boards and to the educational requirements that must precede such examination. Reports of the examinations have already led to ridicule of their content and suggest that the examiners have on occasions been more interested in limiting the number of certificate holders than in determining the fitness of the individual candidate. This ridicule is quite intangible and is always denied, but nevertheless exists and is harmful. It is doubly harmful because it is unnecessary. This movement is too valuable to be spoiled by the thoughtlessness and narrow mindedness of a few examiners, and more care should be taken to see that examinations demonstrate the candidates' fitness to practice rather than the examiners' special knowledge.

In reference to the other criticism noted above, it should be evident and emphasized that any movement looking toward better medicine and surgery for the public must be applicable to the profession as a whole and not to only a chosen few if there is to be any general support for the movement. Pre-examination requirements, for example, that deny certificates as surgeons to all medical school graduates until after they have spent five to seven additional years in a hospital will go far to defeat their own end. While it is

Directory of Medical Specialists: 1939. Edited by F. I. Titus. 1573 pp. New York: Columbia University Press, 1940.

possible, but congested liver unlikely without other positive findings of heart failure

Incidentally, mistaking perihepatitis for acute cholecystitis is a fairly common error, but usually occurs in cases in which there is more tenderness and spasm and the gall bladder is not felt. In this case the palpation of a mass below the liver edge is good confirmatory evidence of cholecystitis.

The blood sugar is not reported as a fasting specimen but even so the patient must have been diabetic. Since the pancreas is under suspicion we should mention pancreatic duct stone and pancreatitis, but there is no record of tenderness posteriorly to support either diagnosis. I do not believe diabetes plays an important part in her illness, but gallstones and acute cholecystitis are commoner in diabetics than in non-diabetics. The normal temperature and pulse and the white count of 10,000 with a four-day story probably mean that the gall bladder was not really acutely inflamed, but they are quite consistent with cystic duct blockage and a tense edematous gall bladder. However it is frequently difficult to correlate the acute or subacute gall bladder found at operation with the history, physical examination and laboratory data. There is no mention of jaundice, and the single attack of persistent pain rather than repeated attacks of colic is against the likelihood of finding a stone of the common duct. SECTION OF OBSTETRICS
AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., *Secretary*
330 Dartmouth Street
Boston

SEPSIS FOLLOWING CESAREAN SECTION

Mrs. M. Z., a twenty-two-year-old primipara was admitted to the hospital October 29, 1933, three hours after the onset of labor. A vaginal examination had been performed at home, at which time the doctor found a floating head.

The patient's health had always been good. She gave no history of system diseases or of serious contagious diseases. There had been no operations in the past. Catamenia had always been irregular occurring every twenty-five or thirty-two days, and were scant in amount of flow. The last menstruation began January 18, the expected date of confinement being October 25.

On entry to the hospital the patient had labor pains coming at five minute intervals. The general physical examination was negative. The heart was not enlarged, there were no murmurs. The pulse rate was 106. The blood pressure was 142 systolic, 82 diastolic. Abdominal examination revealed uterine contractions of moderate severity which lasted forty seconds. There seemed to be a full-term normal pregnancy. The head was overriding the symphysis to a moderate degree, the position was LOP. The fetal heart was regular in action, the rate was 140. The pelvic measurements were as follows: I.C. 28 cm, I.S. 25.5 cm, E.C. 19.5 cm, I.T. 9.5 cm. Rectal examination revealed the cervix to be dilated so as to admit three fingers. The amniotic sac bulged through the external os. The cervix was completely effaced.

The patient was given Nembutal and scopolamine and allowed to proceed in labor. Five hours after entry and eight hours after the onset of labor vaginal examination with aseptic technique disclosed the cervix to be fully dilated, the head to be high and the true conjugate to be 8 cm. An immediate operation was performed under nitrous oxide, oxygen and ether anesthesia. The baby was delivered through a Kerr incision, and weighed 5 pounds, 14 ounces, it was in good condition and was easily resuscitated. The uterine cavity contained yellowish-green material with a very foul odor. A culture was not taken at that time.

A few hours after the operation the patient had a temperature of 102.8°F and was given a clysis

The day following operation she passed a foul smelling yellowish clot, which looked like infected secundines. She was therefore given ergot and was placed in the high Fowler position.

During the first five days after operation the temperature ranged from 100 to 102°F and the pulse fluctuated between 100 and 120. On the seventh postpartum day the temperature went to 105°F rectally, and the pulse rate to 140. A transfusion of 350 cc of citrated blood was given. An other transfusion was given on the tenth day. The abdominal wound drained purulent material, and finally completely broke down so that the uterus could be visualized in the bottom of the septic wound. A culture taken from the wound showed streptococci, staphylococci and colon bacilli. Due to the marked peritonitis from which the patient was suffering she was Ochsnerized. Daily hypodermoclyses and injections of intravenous glucose solution were given. Transfusions were repeated every three or four days.

Two weeks after operation the patient's chest revealed bilateral bronchopneumonia by physical examination, a finding which was corroborated by x-ray. This subsequently subsided.

Abscess cavities eventually developed in both flanks of the abdomen. The one on the left was incised by means of a stab wound just below the costal margin. The abscess in the right lower abdominal quadrant was broken into through the abdominal incision. The wound eventually became free of infection and granulated in under treatment with Dakin's solution.

Two months following the cesarean operation and after two weeks of normal temperature the abdominal wound was repaired by a secondary closure. Parallel incisions were made in the rectus sheaths 1 cm. from the edge of the defect. The inner edges of the incisions were turned toward the midline and were approximated by catgut sutures. The outer cut edges were then sutured together, a procedure which gave two layers of fascia over the granulating area. There was considerable tension, but the wound healed solidly and the patient was discharged approximately three months after entry.

On December 27, 1937, the patient was admitted to the hospital for another cesarean section. The abdominal wound had remained intact throughout this pregnancy. At operation there were no adhesions in the peritoneal cavity. The classical incision was used. The patient had an afebrile convalescence and was discharged in good condition on the seventeenth postpartum day.

Comment. This case of uterine sepsis and peritonitis followed cesarean section. It is unfair to attribute the infection to the test of labor which

* A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

this patient was given inasmuch as it lasted only eight hours and inasmuch as the membranes had not ruptured. It is barely possible that the infection was introduced by the examination performed before the patient reached the hospital. The low cervical operation did not prevent infection. There is no evidence in the record that a temperature existed before delivery, although a temperature of 102.8°F was noted a few hours afterward. It would have been interesting to have had a culture from the yellowish-green material with a very foul odor which was found in the uterus at the time of operation. Had this culture been positive, one would then have known that an infection was present before delivery. The low-grade temperature reported for the first five days after operation leads one to infer that the infection was at that time solely uterine. The temperature rise to 105°F on the seventh postoperative day suggests either that an abscess was forming in the uterus or that there was an extension into the peritoneal cavity. Sulfanilamide might have shortened very materially the convalescence. The secondary operation two months later for the closure of the abdominal wound was successful, as proved by the scar remaining well healed without hernia during the subsequent pregnancy.

It is doubtful under the circumstances whether anyone would have been justified in doing any form of extraperitoneal operation on this case as the record reveals no definite evidence that the operation was being performed on an already infected uterus. In cases where the test of labor has been prolonged beyond twelve hours, particularly with ruptured membranes, some form of extraperitoneal operation is probably the conservative procedure. This case illustrates again the value of repeated small transfusions in septic cases of long duration.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 31

BERKSHIRE

Thursday, April 4, at 4 30 p.m., at the Bishop House of Mercy Hospital, Pittsfield. Gonorrhea in the Female. Instructor Sylvester B. Kelley. Harry G. Mellen, *Chairman*.

BRISTOL SOUTH (Fall River Section)

Tuesday, April 2, at 4 30 p.m., at the Union Hospital, Fall River. Pneumonia. Instructor Charles A. Janeway. Howard P. Sawyer, *Chairman*.

FRANKLIN

Thursday, April 4, at 8 15 p.m., at the Franklin County Hospital, Greenfield. Common Problems

of Neurology. Indications for lumbar puncture. Instructor H. Houston Merritt. Halbert G. Stearson, *Chairman*.

HAMPDEN

Thursday, April 4, at 4 00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 15 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Head and Spine Injuries. Instructor Walter R. Wegner. George L. Schadt, *Chairman*.

HAMPSHIRE

Thursday, April 4, at 4 15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton. Indications for Cesarean Section. Instructor Judson A. Smith. Warren P. Cordes, *Chairman*.

MIDDLESEX SOUTH

Tuesday, April 2, at 4 30 p.m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. The Use of Biological Preparations in Pediatric Practice. Instructor Richard M. Smith. Dudley Merrill, *Chairman*.

NORFOLK

Thursday, April 4, at 8 30 p.m., at the Norwood Hospital, Norwood. Cardiovascular Disease. Eleven important questions about heart disease and their answers. Instructor Marshall N. Fulton. Hugo B. C. Riemer, *Chairman*.

NORFOLK SOUTH

Monday, April 1, at 8 30 p.m., at the Quincy City Hospital, Quincy. Head and Spine Injuries. Instructor Walter R. Wegner. David L. Belding, *Chairman*.

PLYMOUTH

Tuesday, April 2, at 4 00 p.m., in the Nurses' Home of the Brockton Hospital, Brockton. Cardiovascular Disease. Eleven important questions about heart disease and their answers. Instructor James M. Faulkner. Walter H. Pulsifer, *Chairman*.

SUFFOLK

Thursday, April 4, at 4 30 p.m., in John Ware Hall, Boston Medical Library, 8 Fenway, Boston. Syphilis in Pregnancy and the Offspring. Instructor C. Guy Lane. Reginald Fitz, *Chairman*.

DEATHS

GALLAGHER—JOHN H. C. GALLAGHER, MD, of Chicopee, died March 19 at St. Petersburg, Florida. He was in his sixtieth year.

He was born in Leominster and attended the University of Maryland, receiving his degree from Baltimore Medical College in 1903. Before starting practice in Chicopee he spent a year at the Providence Hospital in Holyoke. During the summer of 1907 he studied at the University of London and also at Vienna. In 1910 he received the appointment as medical examiner of the Fifth Hampden District. Dr. Gallagher also studied at the Massachusetts Eye and Ear Infirmary, and was former school physician in Chicopee. He was a past president on the staff of the

Mercy Hospital and had retired from active practice in 1935.

Among his affiliations were fellowships in the Massachusetts Medical Society and the American Medical Association and memberships in the American Academy of Ophthalmology and Oto-Laryngology and the New England Otolaryngological and Laryngological Society.

His widow two sons, his mother, three sisters and three brothers survive him.

LA MOUREAU.—JOSEPH E. LA MOUREAU M.D. of Lowell, died March 16. He was in his seventy-second year.

Born at Chambly, Quebec, he received his education at the College of St. Charles Borromeo in Sherbrooke. He received his degree from the University of Montreal Faculty of Medicine in 1893. Dr. Lamoureux started practice in Lowell immediately after his graduation. For nine years he was a member of the Public Health Council of Massachusetts and a member and president of the former Lowell Corporation Hospital staff. He was the first president of the staff of St. Joseph's Hospital in Lowell. Dr. Lamoureux was a member of the Massachusetts Medical Society and of the American Medical Association.

His widow two sons, two daughters and seven grandchildren survive him.

MIDDLETON.—WILLIS J. MIDDLETON M.D. of East Acton, died March 14. He was in his seventy-third year. Born in Boston he received his degree from Tufts College Medical School in 1901. Dr. Middleton taught anatomy at Tufts College Medical School for five years. A specialist in obstetrics, he taught that subject at the Quincy City Hospital, where he was a staff member for many years. Dr. Middleton was a former member of the Massachusetts Medical Society.

A son, a daughter and six grandchildren survive him.

GREEN LIGHTS TO HEALTH

APRIL—MAY—JUNE

SPONSORED BY THE MASSACHUSETTS MEDICAL SOCIETY AND THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

COURTNEY WAAB—TUESDAYS, 9:45 A.M.

April 2. So You Are Going to the Hospital! John P. Monks.

April 9. Choosing a Camp for Your Child. Warren R. Sisson.

April 16. Hay Fever. I. Chandler Walker.

April 23. What a Health Examination Means. Michael E. Murray.

April 30. Protecting the Teeth of the Child. Paul K. Losch.

May 7. Headache. H. Houston Merritt.

May 14. Alcoholism. Merrill Moore.

May 21. From What Diseases Should Children Be Protected? Edwin H. Place.

May 28. When to Call the Doctor. James M. Faulkner.

June 4. Sulfanilamide: Medicine's new lifesaving drug. Charles A. Janeway.

June 11. Are Vacations Necessary? Alfred Kravetz.

June 18. Why Doesn't Tuberculosis Disappear? Henry D. Chadwick.

June 25. Important Facts about the Fourth. Robert H. Aldrich.

MISCELLANY

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS JANUARY 1940

| DISEASES | JANUARY 1940 | JANUARY 1939 | 5 YEAR AVERAGE |
|---------------------------|--------------|--------------|----------------|
| Anterior poliomyelitis | | 0 | 0 |
| Chicken pox | 2328 | 1433 | 1839 |
| Diphtheria | 35 | 21 | 39 |
| Dog bite | 602 | 509 | 550 |
| Dysentery bacillary | 34 | 70 | 6 |
| German measles | 36 | 67 | 251 |
| Gonorrhea | 342 | 380 | 460 |
| Lobar pneumonia | 620 | 618 | 749 |
| Measles | 961 | 1985 | 1890 |
| Meningococcus meningitis | 3 | 6 | 9 |
| Mumps | 562 | 771 | 902 |
| Paratyphoid B fever | 5 | 0 | 0 |
| Scarlet fever | 565 | 793 | 1004 |
| Syphilis | 431 | 400 | 439 |
| Tuberculosis, pulmonary | 196 | 250 | 282 |
| Tuberculosis, other forms | 8 | 20 | 30 |
| Typhoid fever | 8 | 8 | 6 |
| Undulant fever | 2 | 8 | 4 |
| Whooping cough | 625 | 953 | 983 |

Based on figures for preceding five years.

RARE DISEASES

Anterior poliomyelitis was reported from Boston, 1; Winchester 1 total 2.

Diphtheria was reported from Arlington, 1; Boston 2; Cambridge, 8; Chelsea 2; Danvers, 3; Fall River 5; Lawrence, 8; Methuen 3; North Attleboro, 1; Revere 1; Worcester 1 total 35.

Dysentery bacillary was reported from Beverly 3; Boston, 2; Cambridge, 6; Greenfield, 2; Lynn, 4; Medford, 1; Nauck, 1; Northampton 1; Quincy 1; Reading, 2; Salem 5; Somerville, 1; Sterling 1; Tewksbury 1; Wrentham 1; Worcester 1; Wrentham, 1 total, 34.

Meningococcus meningitis was reported from Boston 1; Medford 1; North Reading, 1 total 3.

Paratyphoid B fever was reported from Boston 1; Holyoke, 1; Lawrence, 1; Newburyport, 1; Pittsfield, 1 total, 5.

Pellagra was reported from Boston 3 total 3.

Septic sore throat was reported from Belmont, 1; Boston, 13; Cambridge, 2; Fall River 1; Lawrence, 1; Merrimac, 1; Northfield, 1; Oxford 2; Plymouth 1; Waltham 1; Winchester 1; Wrentham 1 total 26.

Tetanus was reported from Worcester 1 total, 1.

Trachoma was reported from Boston, 1; Bridgewater 1 total 2.

Trichinosis was reported from Franklin 1 total, 1. Typhoid fever was reported from Boston, 2; Norton, 1; Norwood, 1; Peabody 1; Rockport, 1; Swampscott, 1; Uxbridge, 1 total, 8.

Undulant fever was reported from Freetown 1; Pittsfield 1 total 2.

The incidence of chicken pox was higher than has ever been reported.

Bacillary dysentery primarily of the Sonne type, continued to be prevalent, the level being slightly higher than that of last month.

The level of reported cases of paratyphoid B fever was slightly higher than it has been for the past three months.

There was a continuation of the slight upward trend of diphtheria cases, the incidence being higher than it has been since January 1936.

The reported incidence of measles was well below the five year average.

Scarlet fever had its lowest January incidence since 1919. German measles, meningococcus meningitis, pulmonary tuberculosis and whooping cough were all reported below the five year average.

There was nothing remarkable in the reported incidences of anterior poliomyelitis, gonorrhea, syphilis, lobar pneumonia and mumps

Typhoid fever and undulant fever were reported at expected levels

REPORT OF MEETING

NEW ENGLAND ROENTGEN RAY SOCIETY

A meeting of the New England Roentgen Ray Society was held at the Beth Israel Hospital on December 15, 1939, with Dr Samuel A. Robins presiding

The first speaker was Dr Monroe J Schlesinger, whose subject was "The Roentgenological Visualization of the Coronary Arteries." Attempts to study the configuration of these vessels post mortem were initiated in 1896 and perfected by Gross in 1921. Dr Schlesinger, however, essayed to dissect the heart to duplicate the diaphragms of Spalteholz, so that the coronary arteries might be visualized in one plane. The speaker described his two-colored injection mass and the manner of such dissection of the unfixed heart. Although of the 300 organs thus treated no two showed similar arterial patterns, one was able to place them in three general categories. The first group, which contained 50 per cent of the specimens, had a predominance of the right coronary artery, which crossed to the left side as well as to the posterior septum. In such hearts, two thirds of the infarcts were healed. The second group consisted of fairly well balanced right and left coronary systems and accounted for about 35 per cent of the hearts. In this type there were fewer infarcts, and these were always healed at autopsy. The last group showed a left coronary preponderance, which was present in about 15 per cent of the specimens examined. This was by far the poorest kind of circulation, with the patient dying after infarction in all cases. An important finding was the absence of any anastomoses unless there was evidence of past or present coronary narrowing or occlusion. This indicates that increase of collateral vessels is not a normal concomitant of increasing age and that occlusion is necessary for the development of such anastomoses.

The second paper, by Dr Herrman L. Blumgart, was related to the first and was concerned with the clinical implications of these pathological findings. A correlation of the number of occlusions found at autopsy with the clinical history indicated that patients with angina pectoris had, on the whole, about twice as many damaged arteries as did those without. The severity of symptoms, however, was not always a direct corollary of the organic lesions, for cases were cited of those who carried on in an essentially normal manner despite the thrombosis of two or all three coronary arteries.

Dr Charles G. Mixter presented evidence for "The Value of Cholangiography During Operation." The background for the use of this procedure lay in the increase in choledochostomy from about 8 to 40 per cent due to the number of recurrences following simple cholecystectomy. And since 20 to 30 per cent of these explorations are negative and there is a considerable increase of mortality and morbidity attendant on the procedure, it would be exceedingly beneficial if one could obviate the useless exploration and still be certain before completing the operation that there were no further stones present. Before discussing the results of the roentgenological method, however, Dr Mixter asserted that cholangiography should not replace common-duct exploration when there are definite clinical indications for the latter. Three types of cholangiograms were made: a closed one before ex-

ploration, an open one after exploration but while the patient was still on the operating table, and a postoperative one during convalescence. Although the results with the closed method showed promise, the finding of stones in 7 of 18 cases with negative cholangiograms was considered only a fair result. The open cholangiogram, which was 94 per cent correct, was heartily endorsed.

The next paper was that of Dr Karl Presser on "The Early Diagnosis of Prepyloric Carcinoma." The speaker emphasized that the normal rugal pattern and normal peristalsis of the stomach are functional signs dependent on the integrity of the mucosal, submucosal and muscular structures. Normal rugae may thus be lacking in the presence of submucosal lesions with a normal overlying mucosa. Dr Presser suggested the wider use of serial spot film during the entire course of the peristaltic cycle. A comparison of superficial benign lesions and adhesions with the infiltrative lesions of carcinoma was illustrated by film. Although filling defects may be present in either type of lesion, neoplasms show characteristic abnormalities of the peristalsis, which are consistently visible and not changing even when present in early lesions. Any infiltrating disease may give a similar roentgenogram, and syphilis must be ruled out. Benign tumors are best differentiated by the presence of normal peristalsis during the entire cycle and on repeated examinations. Dr Presser showed the films of three cases in which operations had been performed on the strength of x-ray findings consistent with very early prepyloric cancer, the diagnosis were not confirmed until histological examinations were completed. It was stressed that clinically early cancer often show advanced lesions by roentgenograms because of the accuracy of examining the gastrointestinal tract as a functioning organ by the latter method. Thus, the responsibility of the roentgenologist in the early diagnosis of gastric carcinoma and the importance of serial spot film during the peristaltic cycle were brought out by the speaker.

The next paper on "Changes in the Uterus Following Roentgen Therapy, Demonstrated by Uterotubography" was presented by Dr William S. Altman. The study was based on 15 cases of menorrhagia in which the diagnoses were checked by diagnostic dilatation and curettage prior to irradiation. The same changes from muscular to fibrous tissue were observed in the aged and those subjected to roentgen therapy. The effects might be exerted on the uterus either directly or through the deleterious action of irradiation on the ovaries. Uterotubograms, before and after radiation, demonstrated marked shrinkage of the uterus. All patients experienced relief of menorrhagia within one to two months with doses of radiation varying from 800 to 3200 r, with never more than 1600 r being given in any one series. Three patients required operative intervention for symptoms other than menorrhagia. In summary, Dr Altman stated that 1200 r was probably a sufficient dose and that the severity of the ensuing menopause was probably proportional to the amount of treatment given. The effect was best in patients with a hyperplastic type of endometrium, next best in those with subserous fibroids, and next in those with submucosal fibroids.

The final speaker was Dr Harry F. Friedman, whose subject was "Observations on Contact Roentgen Therapy." There was a description of the apparatus employed, which enables the anode to be within 18 mm of the lesion. The importance of the distribution rather than kind of radiation was stressed. Lesions may be naturally or artificially accessible, bladder lesions being in the latter group. The advantages as enumerated by Dr Friedman consisted of

greater intensity with little reaction a high dosage rate, and a low cost and short duration for the treatment. The time employed was from five seconds to six minutes, and this was cited as being particularly desirable in the treatment of oral carcinoma. About 8200 r of unfiltered radiation per minute can be delivered by the machine. One important consideration is the rapid falling off of intensity with depth, so that only 20 per cent is absorbed unfiltered at a distance of 1 cm. Single dosage, figured on that necessary to destroy the tumor with no attention to the skin has superseded fractional irradiation in this type of treatment. The stated prerequisite for contact roentgen therapy was an accessible lesion which was not too thick. The principle of treatment was to deliver a maximal dose to the tumor base without consideration for the skin. He added that poor permeability accounts for the lack of damage to the surrounding normal tissue.

NOTICES

BOSTON GASTROENTEROLOGICAL SOCIETY

The next meeting of the Boston Gastroenterological Society will be held in the Andrew Carney Hospital Assembly Room of the Carney Hospital on Wednesday April 3 at 12 o'clock noon.

PROGRAM

The Treatment of Peptic Ulcer Complicated by Diabetes Mellitus. Dr. C. W. Finnerty
Rectal Polyps. A pathological discussion. Drs. T. F. P. Lyons and M. Vidoli.
Case Discussion. Dr. A. McKay Fraser
Achochylria. Dr. Louis F. Curran.
Physicians, medical students and nurses are invited.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall 9-10 a.m.

MEDICAL CONFERENCES

Tuesday April 2—Ewing's Sarcoma. Dr. C. P. Roberts.
Thursday April 4—The Use of Staphylococcal Antibiotic in Osteomyelitis with Septicemia. Dr. W. A. MacColl.
Friday April 5—Studies of Radio-Active Iodine in Relation to Thyroid Disease. Dr. Saul Hertz.
Tuesday April 9—Studies on Purpura in Relation to the Spleen and Bone Marrow. Dr. William Dame.
Thursday April 11—Diagnostic Errors. Dr. H. G. Brugsch.
Friday April 12—Prothrombin and Vitamin K. Dr. E. L. Lozner.
Tuesday April 16—The Origin, Diagnosis and Treatment of Pituitary Body Tumors. Dr. Oscar Hirsch.
Thursday April 18—Gastrointestinal Clinic. Drs. K. S. Andrews, H. H. Lerner and L. M. Asher.
Tuesday April 23—Ovarian Tumors. Dr. J. T. Smith.
Thursday April 25—Off the Main Road in Diabetes. Dr. J. J. Schloss.
Friday April 26—Small Bowel Obstruction. Dr. L. S. McKittick.
Tuesday April 30—The Soldier and His Heart. Dr. P. D. White.
Wednesday May 1—Hospital case presentation. Dr. J. E. Paullin.
Thursday May 2—Clinicopathological conference. Dr. C. S. Keefer.
Friday May 3—A Review of Diabetes. Dr. E. P. Joslin.
Saturday May 4—Hospital case presentation. Dr. J. E. Paullin.

On Wednesday and Saturday mornings throughout the month of April Dr. S. J. Thannhauser will give a medical clinic on hospital cases.

For the week April 29 to May 4 Dr. James E. Paullin, professor of medicine at Emory University Atlanta Georgia will act as physician-in-chief pro tem of the Joseph H. Pratt Diagnostic Hospital. He will conduct ward rounds each morning from 8 to 9 o'clock, and give clinics on Wednesday and Saturday mornings, May 1 and 4 from 9 to 10 o'clock.

These clinics are open to the profession and medical students.

GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Tuesday evening April 2, at 8:15.

Dr. Arthur M. Fishberg, associate in medicine, Mt. Sinai Hospital New York City will speak on "Essential Hypertension." A discussion by Dr. Samuel A. Levine, David Davis, David Aymon and Maurice B. Strauss will follow.

WILLIAM HARVEY SOCIETY

The sixth lecture of the season sponsored by the William Harvey Society of the Tufts College Medical School will be given in the auditorium of the Beth Israel Hospital on Friday evening April 5 at 8:00. Dr. Emil Novak, associate professor of obstetrics at the University of Maryland, will speak on "The Endocrine Influence of Certain Ovarian Tumors."

TUFTS MEDICAL ALUMNI LECTURE

The annual alumni lecture will be given at Tufts College Medical School on Wednesday April 3 at 4:00 p.m. Colonel G. R. Callender '08 will speak on "Diarrheal Diseases."

Physicians and students are cordially invited to attend.

CHELSEA NAVAL HOSPITAL

The staff of the Chelsea Naval Hospital will give a clinic for the Colonel Williams Chapter of the Association of Military Surgeons of the United States on Friday evening April 5 at 8:00. The subject will be "Gastrocolic Fistulas." Refreshments will be served following the meeting.

All members of the Association and all members of different branches of the medical services of the United States are invited. Those who expect to attend are requested to notify Major Richard H. Miller, United States Reserve, South Army Boston before March 30.

BOOK REVIEWS

Textbook of Nervous Diseases Robert Bing Translated and enlarged by Webb Haymaker From fifth German edition 838 pp St Louis C V Mosby Co, 1939 \$10 00

Dr Robert Bing, head of the Department of Neurology at the University of Basel, Switzerland, has long been known to English speaking physicians His little book on *Regional Diagnosis*, which first appeared in 1909 and is now in its eleventh edition, has been widely read in its English translation His *Textbook of Nervous Disorders* first issued in 1913 and now in its fifth edition, has not been so well known It is one of the great modern text books of neurology and perhaps takes its place in the first dozen books of its type An English edition has long been anticipated, and one is not disappointed in the translation by Dr Haymaker, who has changed somewhat the form of the book by taking the material out of the lecture form and putting it into various chapters He has added considerable data in regard to anatomy and physiology Several of the chapters have been extensively revised In spite of this, the attractive style of Professor Bing's presentation has not been entirely lost It is difficult to tell, moreover, where Professor Bing's part of the book ends and the translator's begins By bringing new material and augmenting the old material, the translator has added something to the value of the book for English and American readers

The book should be widely read for it contains much material not easily available in other textbooks No neurologist should be without this book, as it is one of the great fundamental texts on the subject

Epidemiology in Country Practice William N Pickles 110 pp Baltimore Williams & Wilkins Co, 1939 \$2 50

The observation that the general practitioner is in a position to make valuable contributions to medical knowledge is commonplace, but it is always pleasant to come on a fresh demonstration of its validity Dr Pickles, of Wensleydale, in the North Riding of Yorkshire, gives us a book which will inevitably bring to mind William Budd's *Typhoid Fever*

A gipsy woman driving a caravan into a village in the summer twilight, a sick husband in the caravan, a faulty pump at which she proceeded to wash her dirty linen, and my first and only serious epidemic of typhoid," he says, "left me with a lasting impression of the unique opportunities of the country doctor for the investigation of infectious disease" That Dr Pickles worthily makes use of his opportunities is apparent from a consideration of his technique, the conciseness and clarity of his statements of fact and the modest assuredness of his conclusions

Just what the "epidemic catarrhal jaundice" that he so carefully studied may be, is, as he himself admits, still sub judice, but he makes out an excellent case for its reality as an entity Epidemic myalgia, or Bornholm disease, is not only an independent discovery of his own, although originally described by an Icelandic practitioner in 1856, and subsequently by several Scandinavians, but a syndrome which in retrospect is recognizable in almost any physician's experience An epidemic at the Massachusetts General Hospital, Boston, was described in the *Journal* in 1933 by Crone and Chapman under the title "Epidemic Pleurodynia"

Apart from its scientific value, this little volume has the added grace of being written in the cursive narrative style characteristic of the best English medical tradition

OXYGEN IN THE TREATMENT OF LOBAR PNEUMONIA

ALEXANDER M. BURGESS M.D.†

PROVIDENCE RHODE ISLAND

IN PNEUMONIA there is often a sufficient degree of anoxia to be definitely detrimental to the patient. This may be a factor of sufficient importance to decide the issue between recovery and death. The administration of oxygen will often completely relieve this anoxia. One must therefore consider the use of oxygen in this disease as an accessory method of treatment which, in the severer cases, may be indispensable.

Anoxia in pneumonia is of the arterial anoxic type, that is to say, it is due to interference with the passage of oxygen into the blood, so that the fact of a decreased oxygen supply to the tissues is due to a desaturation of the hemoglobin. This is the type of anoxia in which the inhalation of oxygen-rich air is effective—as opposed to anemic anoxia, in which the oxygen-carrying power of the blood is diminished, and to stagnant anoxia, in which the velocity of capillary flow is decreased. Anoxemia in pneumonia may be the result of three main factors, or more usually a combination of the three. It may result from an insufficient amount of oxygen entering the alveoli because of shallow breathing due to acute pleurisy. It may also be due to a partial shunting of unoxygenated blood through a lobe in the stage of early or red hepatization, when exudate in the alveoli prevents the entrance of air but circulation through the affected lobe is still maintained. Of course oxygen is effective only in so far as it can reach the unsaturated hemoglobin, and in cases where air is completely excluded from lung tissue, through which blood still flows, increased oxygen tension in the air is of no value. But it is probable that such a shunting is not often a dominant factor, and when it does occur oxygen-rich air certainly can aid in controlling the general desaturation that results from the dilution

of the unoxygenated blood which has passed through the affected lobe into the rest of the patient's general circulation. The third and principal cause of the anoxemia in pneumonia is probably widespread congestion and edema which make the lumens of the bronchioles smaller and the alveolar walls less permeable. In such cases an increased tension of oxygen in the air that gets into the alveoli means an increase in hemoglobin saturation and a decrease in anoxia. It is in the severe and late cases, and especially in those in which there is a spread of the pneumonia to several lobes or an added factor of cardiac weakness, that oxygen is of the greatest value.

I propose to present a brief summary of the effects of anoxia in pneumonia, and to consider the main indications for oxygen therapy and the simpler and more effective methods of carrying it out. While I shall speak of the clinical results of this treatment in general, I shall make no attempt to present any statistical evidence as to the value of oxygen in pneumonia. Stadie,¹ in 1922, in emphasizing the value of this type of therapy, pointed out that it did not lend itself to statistical analysis. At the present time, when both adequate serum therapy and sulfapyridine are proving their worth in such spectacular fashion it is quite impossible to determine the value of an accessory factor such as oxygen by any study of mortality figures. It is my purpose, also, to mention very briefly the use of high concentrations of oxygen in the treatment of abdominal distention, which is such an appalling complication of some cases of pneumonia.

That marked arterial unsaturation exists in many cases of pneumonia was demonstrated as early as 1912 by Hurter. This anoxemia has been shown to be as great as that which, when brought about experimentally, produced severe symptoms. Its action on the nervous and circulatory systems is of particular importance. Anoxia occurring in pneu

*This section meeting was held and the following two papers read during the annual meeting of the Massachusetts Medical Society, Worcester, Massachusetts, June 6, 1939.

†Visiting physician, Rhode Island and Charles V. Chapin hospitals, Providence.

monia affects the nervous system by producing symptoms the most prominent of which are headache, neuromuscular weakness and delirium. It is well to remember that in very toxic patients such symptoms are often due not to the toxemia but to the anoxia, and therefore may be preventable or correctable by oxygen. The effects on the circulatory system are equally important. As Meakins,² Long and Evans³ and others have pointed out, reduction of oxygen supply is the only factor that can be shown definitely to reduce cardiac gly-cogen and thus to reduce the efficiency of the heart. In elderly patients, especially, this is of significance in pneumonia. Clinically, anoxia is ordinarily seen to produce tachycardia, and it is usually observed that oxygen which causes cyanosis to disappear in pneumonia also reduces the pulse rate. Other effects of anoxia which are of importance in pneumonia are nausea and vomiting, and an increase in the rate, and to a less extent in the depth, of respiration.

The best clinical gauge of the extent of the anoxia in pneumonia is the degree of cyanosis. Roughly speaking, cyanosis that is just recognizable means a desaturation of about 10 per cent, that is, the normal saturation of 95 per cent has been reduced to 85 per cent. If cyanosis is very marked it may mean a desaturation below 70 per cent. Cyanosis, then, may be considered the cardinal indication for oxygen therapy. Dyspnea, however, also may be considered an indication if it is marked. Barach and Levy⁴ have called attention to the fact that in heart disease a potential anoxia may be present, but that by extra respiratory effort actual anoxia may be prevented. Such effort is exhausting and an extra load on the heart. In pneumonia, I believe, the same situation exists, and if dyspnea is severe, even without cyanosis, an attempt to relieve it by oxygen should be made.

Any method that sufficiently increases the oxygen tension in the inspired air and is not too disturbing to the patient is adequate. So far as I know, no method of giving oxygen intravenously over a long period that is practical or safe has been developed. Subcutaneous oxygen was studied a few years ago in our clinic, and appeared to be quite ineffective in relieving anoxia clinically or in decreasing the desaturation of the blood. This method has recently been studied experimentally by Barker and his associates,⁵ who reached the same conclusion. Among the methods of giving oxygen by inhalation I shall consider three: masks or face inhalers, nasal or oropharyngeal insufflation and the open box. Oxygen of course may be given effectively by one of the large tents or by placing the patient in an oxygen room. Such methods are excellent, but the equipment is so ex-

pensive that in a general hospital it is usually impossible to maintain enough of it to serve the many patients who need oxygen.

Masks or facial inhalers of various sorts have been employed for many years, and some have proved fairly efficient. The B.L.B. mask, oronasal type, which has been recently developed at the Mayo Clinic by Boothby, Lovelace and Bulbulian,⁶ has seemed to me by far the best yet devised.⁷ Recent tests that I have made have convinced me that this apparatus is very efficient, and many patients tolerate it very well. Furthermore, it is less wasteful of oxygen than are most of the other methods.

In utilizing the nasal catheter I have for years employed the method of oropharyngeal insufflation of Wineland and Waters.⁷ I have followed their technic carefully and have found the method usually well tolerated by most adults. The studies of Barker, Parker and Wassell on the alveolar air in patients treated by this method have shown that in order to obtain a therapeutically effective concentration, a flow of at least 4.5 to 6 liters per minute must be maintained, in some cases this must be increased to 8 or 10 liters. I have thought that in general this method was the best for the average adult, but if the need for oxygen is great the open box or the B.L.B. mask should be used. While the testing of the latter apparatus is not yet by any means completed, I have gained the impression that it is even slightly more efficient as to the delivery of oxygen than is stated by its originators.

The open-box method⁸ is the one of choice for infants and children. It is also effective in adults and in my clinic is employed in those cases in which a higher concentration of oxygen is needed than can be easily obtained by the nasal catheter. In the future it is probable that many such cases can be better treated by the B.L.B. mask. In most of the adult cases of pneumonia, however, oropharyngeal insufflation has been found satisfactory. In using the open box or any tent, it is of particular importance, as Barach and Levy⁴ have emphasized, to know exactly what the patient is getting, and tests of the oxygen content of the air in the apparatus should be routinely carried out at regular intervals. Many of the disappointing results of oxygen therapy are due to improper application of apparatus.

A review of the last 300 cases (up to February 1939) diagnosed as lobar pneumonia at the Rhode Island Hospital shows that 142 patients (47 per cent) received oxygen at some time during the course of the disease. Of the patients treated with

⁶It is to be noted that the oronasal and not the nasal type of B.L.B. mask should be used, as one cannot trust a sick patient not to breathe through the mouth.

oxygen, 90 received it by the open-box method, and 52 by the catheter method. Most of those on whom the open box was used were children, and all those who received oxygen by nasal catheter were adults. The open box was, however, of great value in a few of the more desperate cases in adults in whom treatment by nasal catheter seemed inadequate.

A further use of oxygen in pneumonia, fortunately a rather rare one, remains to be mentioned, namely high concentrations for the relief of abdominal distention, as suggested by Fine and his associates.¹¹ I¹⁰ have described a modification of the box method by which 98 per cent oxygen can conveniently be given, and recently Congdon and I¹¹ have reported the clinical results in 40 cases treated by this means. Although severe distention usually in our experience, can be relieved by ordinary means,—enemas and peristaltic stimulants,—we think that occasionally, when such means have failed, high oxygen concentrations may be life saving.

SUMMARY

In the treatment of lobar pneumonia, oxygen therapy is an accessory method of considerable value that is occasionally indispensable. Its value lies in the relief of the deleterious effects of anoxia, especially on the nervous and circulatory systems.

Cyanosis is the best clinical sign in determining the presence and degree of the anoxia in pneumonia, but severe dyspnea, even without cyanosis, is also an indication for the use of oxygen.

The most practical and inexpensive methods for giving oxygen are oropharyngeal insufflation through a nasal catheter, and the open box. To these must now be added the new B.L.B. mask, which appears to give very excellent results.

At the Rhode Island Hospital during the last three years almost 50 per cent of all patients with the diagnosis of lobar pneumonia have received oxygen either by nasal catheter or by open box. In the rare cases in which marked abdominal distention occurs, unrelieved by ordinary measures, 95 to 98 per cent oxygen given by the closed-box technic may relieve the situation.

ATYPICAL BRONCHOPNEUMONIA OF UNKNOWN ETIOLOGY*

Possibly Due To a Filterable Virus

MICHAEL E. MURRAY, JR., M.D.†

CAMBRIDGE, MASSACHUSETTS

DURING the academic year 1936-1937 the physicians associated with the Department of Hygiene of Harvard University observed a mild form of pneumonia which differed strikingly from pneumococcal lobar pneumonia and likewise from the usual types of bronchopneumonia. We had seen a few cases during the previous academic year that probably belonged in the same category. In the following college year the incidence of such cases increased, and during the fall and winter of 1938-1939 we saw a still larger number (Table 1) ‡ Bock¹ has called attention to this in his account of our experience with acute infections of the upper respiratory tract in 1938. There has been considerable speculation as to whether this form of

pneumonia constitutes a separate disease entity, and also as to its etiology. It has been referred to

TABLE 1 Cases of Atypical Bronchopneumonia Treated at Stillman Infirmary during the Academic Years 1935-1936 through 1938-1939

‡Associate in medicine, Massachusetts General Hospital.

monia or pneumonitis have appeared in the literature. Most of the descriptions are quite similar to our own observations, but the cases described by Cass² and Reimann³ differed in some respects. The patients reported by Cass had marked prostration at the beginning of the illness, rather early appearance of the physical signs and a true leukopenia. Those reported by Reimann were very severely ill and seemed to have had a much more virulent infection than the ones we have seen. Those reported by Gallagher,⁴ Bowen,⁵ Allen⁶ and Smiley et al.⁷ and the group we have observed are strikingly similar. It is interesting that Stansfield⁸ in 1923 published some observations on a series of patients who had an infection closely resembling the one we are describing.

In an attempt to describe the clinical picture we have reviewed the histories of 132 cases, all of which were treated in the Stillman Infirmary of Harvard University during the last four years.

CLINICAL PICTURE

The illness usually starts as a mild acute infection, resembling "grippe," in which symptoms referable to the respiratory tract are mild or absent. The patient does not have the appearance of one who is developing a pneumonic process. The usual story is that during the preceding day or two he has had some headache, malaise, a little fever and perhaps mild chilly feelings, together with peripheral aches and pains. He may have had a slight cough, but this is frequently so mild that it is not mentioned by the patient unless he is questioned on the point. There is generally little sputum and no history of chest pain.

The physical examination reveals little except slight reddening of the pharynx and an elevated temperature. The pulse is not particularly elevated and the respiratory rate is normal. The diagnosis is usually made by x-ray on the third or fourth day, when a patch of hazy dullness is found in one lung field. It is well to remember that even at this stage there are no abnormal physical signs to be found on examination of the chest. There is some cough and perhaps a small amount of mucopurulent sputum. The sputum is not bloody or rusty.

The temperature returns to normal by the sixth or seventh day, and by this time coarse rales may be heard over a localized area. The patient remains in bed another week, is gradually allowed to resume activity, and at the end of another week to ten days has returned to a normal state of well-being.

A review of the details of the histories of these patients reveals that less than half of them had

had a cold or other respiratory infection during the previous three weeks (Table 2). About one quarter of them had had a relatively sudden onset, feeling moderately ill in the course of twenty-four hours or less. The explosive onset seen in lobar pneumonia did not occur. The remainder gave a story of the gradual development of symptoms over the course of two or three days. Occasionally the patient had been sick for a week or more with what he considered "grippe" or a bad cold, and had either been taking care of himself in his room or going to classes. He showed evidence of

TABLE 2 *Onset, Preceding History and Presenting Symptoms in 132 Cases*

| CLINICAL FACTOR | NO. OF CASES |
|------------------------------------|--------------|
| Onset | |
| Sudden (24 hours) | 35 |

either a fully developed or resolving pneumonic process when first seen. This occurred in 6 cases. Almost all the patients developed a slight cough within the first few days. Headache, which might be severe, was very common; it was frequently frontal and occasionally unilateral. Some degree of peripheral aches and pains was present quite frequently, with a few cases of marked lumbar pain. Aching in or about the eyeballs was quite marked in several cases. Mild sore throat was relatively common and coryza might be present, but this was infrequent. Some patients complained of a slight tightness of the chest or substernal discomfort, but any degree of real chest pain was exceptional. Only a few experienced a shaking chill, although chilly feelings or chilliness occurred rather frequently. A small number had gastrointestinal symptoms at the beginning: nausea and vomiting, or diarrhea. Sweating was frequently present at the onset and sometimes became marked later in the illness. Prostration was occasionally present to some degree, but in general the picture was that of a mild infection.

The initial physical examination was noteworthy because so regularly normal. A temperature of 100 to 101°F and a little pharyngeal red

dening were the only frequent positive findings. A tinge of cyanosis was observed in only a few cases. Respiratory distress was absent and examination of the chest was normal. The abdomen was soft and flat. A palpable spleen was noted in a few cases.

The course of the disease was variable. In a small number of cases the temperature dropped to normal in the first twenty-four to forty-eight hours after the patient went to bed, and remained normal thereafter. Sometimes the temperature fluctuated irregularly, rising as high as 104 or 105°F., but usually covering a range of 101 to 103 and remaining elevated for five to seven days. The pulse rate was low in proportion to the fever, and was frequently a very reassuring sign in the few patients who appeared to be seriously ill. The respirations were almost never significantly increased. This was one of the most constant findings in these cases. During the earlier part of the febrile period considerable headache with some malaise and sweating was present, and later intermittent bouts of cough with varying amounts of sputum were common. The patient's subjective discomfort, however, was less than one might expect on casual inspection of the temperature chart and x-ray film.

In a little more than half the cases physical examination of the chest revealed dullness on percussion. This usually appeared on the second to the fifth day and was frequently barely detectable. Marked widespread dullness appeared in only a small proportion of the cases. Breath sounds were normal at the beginning, but tended to become diminished with the progress of the disease and in some cases were almost suppressed. Some degree of diminution of breath sounds was found in a majority of the cases, but any marked bronchovesicular or frank bronchial breathing was uncommon. The development of bronchial breathing sometime in the course of the illness was observed in only 15 per cent of the cases, and when present often disappeared in twenty-four to forty-eight hours. Significant alterations of the tactile fremitus and marked changes in the whispered and spoken voice were likewise found only occasionally. Rales were late in appearing, not being heard until the fifth, sixth or seventh day in bed, and sometimes not until the eighth to twelfth day. The rales were coarse and were apt to persist for one or two weeks before completely clearing. A small proportion of the cases never developed any abnormal physical signs.

Although in most cases the sputum was very scanty throughout the course of the illness, the production of profuse, mucopurulent sputum occurred occasionally. No significant degree of

tympanites was encountered in any of the patients. Nervous symptoms, such as those described by Reimann,³ we have not seen at all. In a few cases there was extension of the process to another lobe, but this was exceptional.

The average duration of infirmity care was ten to fourteen days. Several patients had a rather desultory, lethargic course with prostration and ran a low grade fever for two or three weeks. These required a prolonged convalescence. Severe reactions with great prostration, prolonged high fever or the appearance of critical illness were rare.

The following abstracts are illustrative of typical cases.

CASE 1. E. P., a college student, aged 21, was admitted to the Stullman Infirmary on November 23, 1938. He had had a "cold" beginning 2 days previous to admission. The day before entry he had had chilly feelings, a sensation of tightness under the sternum and a dry hacking

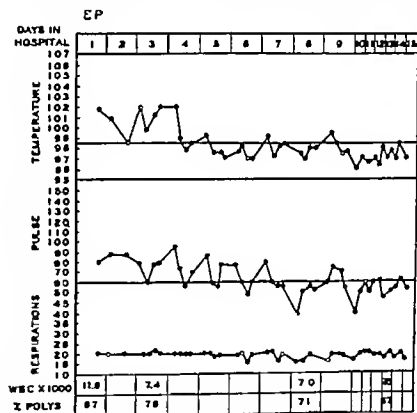

CHART 1

cough. He had some headache, fatigue and mild malaise when first seen. He had had no sore throat, chest pain or sputum, and he did not feel particularly ill. On admission the temperature was 102°F., the pulse 80 and the respirations 20 (Chart 1).

Physical examination revealed a young man sitting up in bed in no particular discomfort other than an occasional cough. The skin was warm and moist. There was no adenopathy. The nose and throat were essentially normal and examination of the chest was negative. The rest of the physical examination was essentially normal. An x-ray film of the chest taken on the 3rd hospital day revealed an area of soft, hazy density at the right base occupying the cardiac angle (Fig. 1).

On the 3rd and 4th hospital days the patient had rather severe headache, perspired freely and felt moderately sick. His cough was more marked and he was producing small amounts of mucopurulent sputum, which was

not bloody On the 5th day slight dullness to percussion and a moderate number of coarse, moist rales were found at the right lung base posteriorly At this time the temperature dropped to normal, the headache had subsided and the patient felt very much improved Thereafter he made steady improvement and had an uneventful recovery The dullness disappeared after a few days, but coarse, moist rales persisted until the 12th day The patient was

coarse, moist rales appeared in the right lower chest, and a small number were also heard in the left lower chest. The rales persisted until the 12th day The patient was

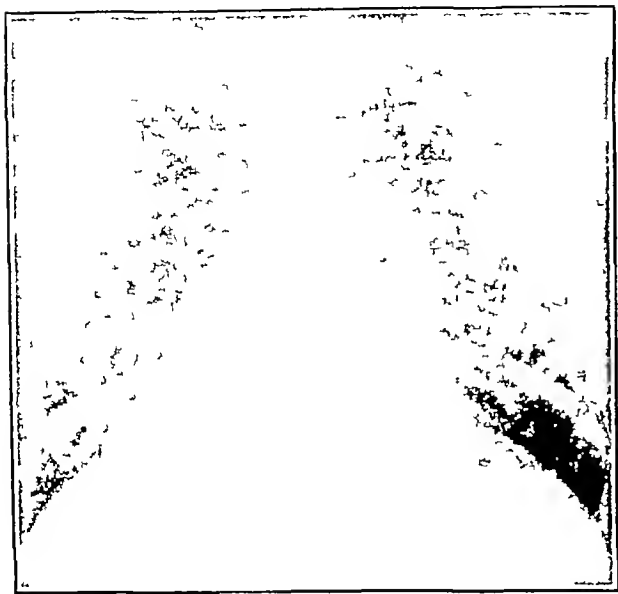

FIGURE 1 Case 1

This chest film was taken on the third hospital day

discharged on the 15th day and returned to his classes 1 week later

The sputum contained pneumococcus, Type 6 There were no complications

Comment This patient represents a fairly typical mild case. The lesion occupying the cardiophrenic angle was a very common finding in such cases

CASE 2 P S, a college student, aged 20, was admitted to the Stillman Infirmary on November 28, 1938 Ten days previously he had had some coryza and sore throat. This had subsided, but for the week preceding admission he had had some cough without expectoration For the previous 3 days he had felt that he had some fever but very little malaise.

The day of admission the temperature was 100°F, the pulse 80, and the respirations 20 (Chart 2) Physical examination revealed a young man who was coughing but who did not appear to be very ill A few fine rales were heard at the base of the right lung, but there were no other abnormal physical signs

The temperature rose to 102°F the day after admission and the patient felt moderately ill At that time some dullness to percussion and diminution of breath sounds were found at the right lung base. An x ray film revealed a large area of density extending upward and downward from the right hilus along the right border of the heart (Fig 2) By the 3rd day the patient felt very much improved, and except for some persistence of the cough had very few symptoms thereafter He continued to have an irregular temperature up to 101°F, but this had returned to normal by the 6th day Numerous medium and

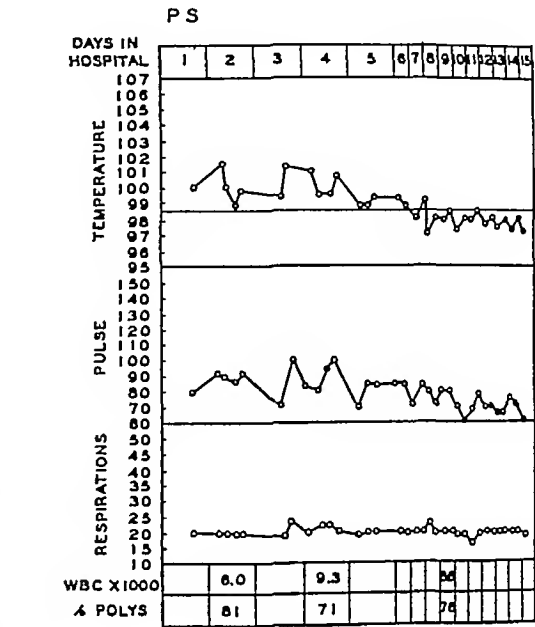

CHART 2

discharged on the 15th day to continue convalescence with relatives

No pneumococci were found in the sputum. There

FIGURE 2 Case 2

This chest film was taken on the second hospital day

was an uneventful recovery without any complications.

Comment This patient also is an example of a fairly typical mild infection. The pulmonary lesion presumably began several days before the patient went to bed. The x-ray film illustrates the fan proceeding from the hilus, which has been described by others

CASE 3. G. M., a law student, aged 22 entered the Sullman Infirmary on September 27, 1938. He had felt well up to the previous day, when he had suddenly begun

the chest was negative. The physical examination was otherwise essentially normal.

On the 2nd day the patient still had considerable head-

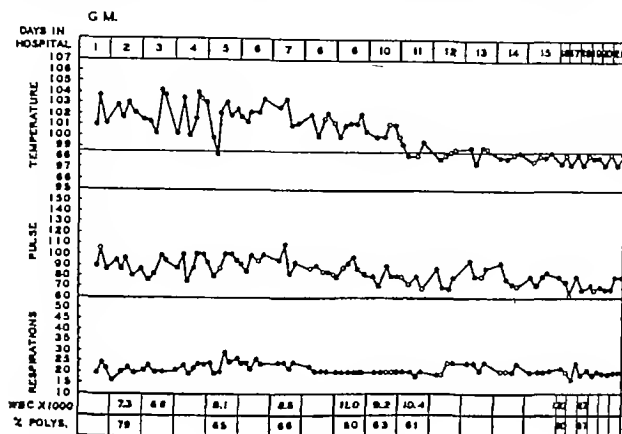

CHART 3

to have aches and pains in his muscles and all over his body developed some headache, and felt feverish. During the night he perspired freely and the next morning

ache and developed a little cough. An x ray film showed an indefinite area of density extending down from the right hilus to the cardiophrenic angle. He continued to have an irregular temperature, up to 104 F had considerable cough and headache, and perspired freely. On the 5th day some dullness to percussion and diminution of breath sounds were found over the right lower chest. A second x ray film taken the same day showed considerable increase in the consolidation at the right lung base (Fig 3). On this day the temperature dropped to normal. This was shortly followed by a chill and the temperature again rose to 103 F.

The patient continued to feel moderately ill, with profuse perspiration and severe headache. The cough persisted, and he raised moderate amounts of mucopurulent sputum, which on a few occasions was blood streaked. Abnormal physical signs became more marked and on the 7th day there was dullness posteriorly extending downward from the angle of the scapula with a moderate number of medium moist rales in that area. A third x ray film taken on the 10th day showed a slight increase in the amount of density over the previous observation. The patient continued to have an irregular fever which gradually subsided by lysis, reaching normal on the 12th day. Large numbers of medium and coarse, moist rales appeared throughout the entire right lower chest, persisting until the 19th day. There was no bronchial breathing at any time. The white-blood-cell count which had been within normal limits, rose to 17,000 on the 16th day.

The patient was discharged on the 21st day to Lyman House for convalescence. He had lost 12 pounds and felt rather weak, but otherwise was symptom-free. He had an uneventful convalescence and no complications.

Repeated sputum examinations revealed no pneumococci.

Comment This patient was moderately ill and probably had a spread of the process about the 5th day. The relatively low pulse and respiratory rates, the absence of

FIGURE 3. Case 3

This chest film was taken on the fifth hospital day

felt better. He went to his classes, but during the morning felt very sick with general malaise and fever.

At admission the patient felt moderately ill but had no cough. The temperature was 101 F., the pulse 90 and the respirations 20 (Chart 3). The skin was hot and moist. The pharynx was moderately reddened. Examination of

pneumococci in the sputum and the normal white blood-cell counts, with a rise to 17,000 on the sixteenth day, are of interest.

CASE 4 R H., a graduate student, aged 28, was admitted to the Stillman Infirmary on March 18, 1939. One

many alpha hemolytic streptococci and small numbers of staphylococci and *Neisseria catarrhalis*. Two blood cultures were negative. A Widal test was negative. The white blood-cell counts were consistently normal.

The patient was discharged April 8. There were no complications, but the convalescence was prolonged.

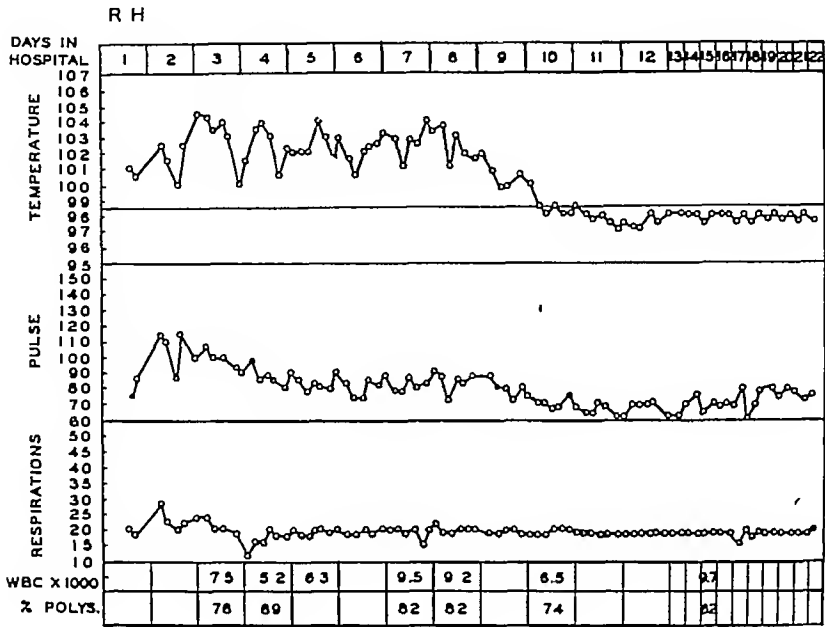

CHART 4

month previously he had had an upper-respiratory infection and had been in bed for 1 week. However, he made a complete recovery and felt well until the day before admission. On that day he experienced a tight sensation in his chest. The following day he found that he had a fever and therefore came to the infirmary. He had mild coryza, considerable malaise and ached all over. He had no cough.

Physical examination revealed a man who looked sick. The temperature was 101°F, the pulse 75, and the respirations 20 (Chart 4). The skin was hot and dry. There was slight nasal discharge, the tongue was coated and dry, and the pharynx showed mild generalized reddening. A few small lymph nodes were palpable. Examination of the chest was negative.

On the 2nd day in bed the patient developed a slight, dry cough, had a chill, and the temperature rose to 104°F. He had no appetite and felt prostrated. An x-ray film of the chest taken on the 3rd day showed a small area of haziness at the right cardiophrenic angle. During the next 3 days he had some nausea, vomiting and diarrhea. On the 5th day, slight dullness and bronchovesicular breathing were heard over the right lower chest. The physical signs increased, with marked dullness all over the right lower chest, bronchial breathing and increased whisper. Tactile fremitus was equal on both sides.

The patient continued to have an irregular fever, ranging from 101 to 104°F, for 8 days. He was listless, apathetic and prostrated by the illness. X-ray films showed an increase in the consolidation, which occupied the position of the middle lobe and a portion of the lower lobe of the right lung (Fig 4).

Repeated sputum examinations were negative for pneumococci and acid-fast bacilli. Sputum culture revealed

Comment This man felt and looked severely ill. The relatively slow pulse was reassuring, and the normal leuko-

FIGURE 4 Case 4

cyte count throughout the illness is of interest. Severe illness such as this case illustrates was seen rarely in this series.

ROENTGENOLOGICAL OBSERVATIONS

Since we frequently did not suspect a pulmonary lesion for several days, it has been difficult to determine accurately how soon x-ray changes can be detected after the illness begins. In a few cases where x-ray films were taken early, changes were found within twenty-four hours after the initial symptoms. Certainly x-ray changes are present for several days before abnormal physical signs can be detected. The roentgenogram usually discloses an area of hazy density extending out from the hilus region into the lower lung field, and occasionally into the midlung field. The margins of this area are ill defined, shading off gradually into the surrounding normal lung. As the disease progresses, the area increases in density, may increase in size and becomes more sharply defined. Resolution occurs as in other types of pneumonia, the density gradually diminishing and becoming more mottled and linear in type. A week to ten days after the peak of the illness the lung may show only a few linear bands of density in the previously involved area. The characteristic finding is lobular rather than lobar distribution of the lesion. Although a whole lobe was involved in a few cases, the majority showed only a section of one lobe to be affected. Basal lesions were commonest, upper lobe lesions were observed in only 9 cases. Lesions, usually termed central pneumonia, limited to the hilus region were found in 13 cases. More extensive shadows occupying the midlung field but not reaching the base were observed in 17 cases. The remaining lesions occupied either the right or left lower lung field, being found more frequently on the right. Bilateral lesions were observed in 13 cases. In the cases of patients who ran a mild clinical course it was quite common to find a small area of consolidation limited to one cardiophrenic angle. Evidence of consolidation and collapse were found in 7 cases.

LABORATORY DATA

The average case presented a normal or slightly elevated leukocyte count. Seventy-five per cent of the patients had an initial leukocyte count of 5000 to 12,000, the majority being from 7000 to 11,000. The percentage of polymorphonuclear cells was usually 70 to 75. Among those who had an initial leukocyte count higher than 12,000 were several patients with walking pneumonia,* several who had had an antecedent infection in the sinuses, pharynx or middle ear, and those who had been vomiting. In one third of the cases in which the initial leukocyte count was not over 12,000 there was a curious rise in the count during convalescence, occasionally reaching 17,000 to 20,000. While

this might be taken to herald the onset of some complication, none appeared in this group. The percentage of polymorphonuclear cells found after the leukocyte count had risen was only slightly increased.

Through the facilities of the Massachusetts Department of Public Health we were able to have sputum examinations made on a large number of cases, but owing to several factors we were unable to carry out extensive bacteriological studies. Seventy sputum examinations were made in 53 cases, 41 of which were reported to contain no pneumococci and 29 to contain varying numbers of one or more type specific pneumococci. No cases of Type 1 were reported, but 1 of Type 2 and 1 of Type 3 were found, and the remainder were scattered throughout the higher types—Types 4 to 32. Sputum cultures were done in a small group of these cases at the Massachusetts General Hospital, and a variety of organisms which can be found in any nonspecific respiratory-tract infection were reported.

In 11 cases* Enders, Sullivan, Hammon and Meakins,³ of the Department of Bacteriology, Harvard Medical School, attempted to demonstrate an etiologic agent by the inoculation of a variety of laboratory animals, including mice, rabbits, guinea pigs, ferrets and *Macaca mulatta* and of the chorio-allantoic membrane of the hen's egg. The injection of blood, sputum and nasopharyngeal washings failed to induce in these species any recognizable pathologic changes.

Routine urine analyses were done on admission and at intervals throughout the infirmity stay. These were all negative except for occasional transient albuminuria and very occasionally, small numbers of red blood cells in the centrifuged sediment.

TREATMENT

The basis of treatment has been the ordinary measures usually instituted in simple acute infections—bed rest, liberal fluids and normal diet, with added sodium chloride when there was any marked salt loss through perspiration. Codein has been used to help control cough, and the salicylates have been used to control the aching and malaise so common during the early part of the disease.

Oxygen therapy has not been necessary in any case, specific serum has not been used. Sulfanilamide was used in 1 case without benefit, and sulfapyridine was not used.

COMPLICATIONS

One of the most striking features of the clinical picture was the absence of any serious complica-

*This group was made up of students at the Stillman Infirmary and nurses from a Boston hospital.

tions In 1 case we had x-ray evidence of questionable fluid, but in no case did we note the occurrence of empyema In 8 cases either marked follicular tonsillitis, acute sinusitis or otitis media was present when the patient was admitted to the infirmary, the pneumonic process either developing or being discovered subsequently Sinusitis of moderate degree occurred in the course of the illness in 4 cases Mild otitis media not requiring paracentesis occurred in 5 In 2 cases it was more severe, one requiring paracentesis and the other draining spontaneously Mastoiditis did not occur Urticaria occurred in 1 case Ulcerations on the soft palate were observed in 1 case In 1 case streptococcal pharyngitis with cervical adenitis occurred

There were no deaths in this series *

EPIDEMIOLOGY

During the academic year 1938-1939 a detailed follow-up study on 45 of the patients was carried out by Ernest B. Millard, Jr., and James H. Mitchofer,¹⁰ students at the Harvard Medical School They noted that the highest incidence of the pneumonia cases occurred in November and December, whereas the highest incidence of other respiratory infections occurred in February and March This suggests that the illness in question is not etiologically related to the common cold They were able to trace eight miniature epidemics in which exposure and contacts were studied carefully, and concluded that the infection is contagious, though not highly so, and is probably transmitted from one person to another by direct, casual contact. Because of the presence of multiple contacts, determination of an incubation period could not be carried out with any degree of certainty, but in four series of cases where multiple contacts were few, evidence was found to suggest an incubation period of seven to eleven days

SUMMARY

During the last four years a rather mild form of pneumonia has been observed among the students at Harvard University During the academic year 1938-1939 it was much more prevalent, 81 cases having been cared for in the Stillman Infirmary and 39 cases reported by family physicians The records of 132 infirmary patients have been studied with a view of describing the clinical course of the illness

It began as a simple acute infection, with min-

During the four years under consideration there have been 235 cases of pneumonia of all kinds occurring among Harvard students. This includes patients taken care of by their own physicians at home or in hospitals and those at Stillman Infirmary Three deaths occurred all in the year 1935-1936 one a Type 1 lobar pneumonia, another a Type 3 lobar pneumonia and the third an overwhelming streptococcal pneumonia.

imal respiratory symptoms, but usually with the early appearance of cough and later some degree of expectoration The chill, chest pain, bloody sputum and prostration of pneumococcal lobar pneumonia were as a rule absent A pulmonary lesion, most often beginning at the hilus and advancing outward toward the lateral chest wall or the diaphragm, was demonstrable early in the illness by x-ray examination Physical signs were minimal, and absent altogether in certain cases When present, they were late in appearing Mild dullness to percussion, some diminution in breath sounds, followed by the appearance of coarse rales on the fifth, sixth or seventh day, were the usual findings The course was ordinarily mild, with return of the temperature to normal in five to seven days The pulse was only moderately accelerated, rarely rising above 90 or 100 The respiratory rate was almost invariably normal Severe prostration was present in a few cases, but tympanites, delirium and other evidences of critical illness were not seen

The leukocyte count was either normal or slightly elevated, with 70 to 75 per cent polymorphonuclear cells In about one third of the cases there was a rise in the leukocytes during the latter part of the illness without the appearance of complications to explain it Complications were few, and when present were mild The more serious complications, such as empyema, lung abscess and bronchiectasis, did not occur The majority of sputum specimens examined contained no pneumococci, somewhat less than half showed a pneumococcus, usually one of the higher types Sputum cultures yielded a variety of organisms, and a small number of blood cultures were all negative Attempts to isolate a filterable virus were unsuccessful

A short convalescence with relatively rapid return to normal daily living was the rule No deaths occurred

We believe that this infection represents a separate disease entity, but judging from other reports, do not believe that it is a new disease. It does not appear to be related to the common cold, nor to epidemic influenza Epidemiological observations indicate that it is contagious and suggest an incubation period of seven to eleven days What bacteriological studies have been done fail to incriminate any of the known bacteria as etiologic factors This negative evidence, plus certain characteristics of the clinical picture, at least suggest that this is a virus disease So far, however, no positive evidence in favor of this impression has been obtained

SULFANILAMIDE THERAPY IN CHRONIC UNDERMINING STREPTOCOCCAL ULCER*

Report of a Case

KNOWLES B. LAWRENCE, M.D.†

BOSTON

CHRONIC, undermining, streptococcal ulcers, though uncommon in general practice, offer a real problem in therapeutics. Numerous bacteriostatic and bacteriocidal drugs, vaccines, maggot, radiation therapy, and even surgical and electrosurgical excision, have frequently enough proved ineffectual in preventing the spread of these ulcers.

The comprehensive studies of Meloney and his co-workers¹⁻⁴ have added much to the knowledge of this condition. In his experience a microaerophilic, hemolytic streptococcus has been the principal bacterial agent. He found that zinc peroxide, which liberates nascent oxygen in close proximity to these organisms buried in the infected ulcer tissue, was very effective in healing many of the ulcers. At least two other authors^{5, 6} report success with this preparation. It is evident, however, that not all these ulcers are cured by zinc peroxide.⁷ The acknowledged variability in the oxygen liberating potency and therapeutic efficiency of commercially available zinc peroxide may be one reason for this failure. Furthermore, the technical requirements necessary for the successful application of this drug as outlined by Meloney may prove difficult in the home and in some small hospitals.

Experience with the case to be reported and that of Goodman⁸ indicates that sulfanilamide is very effective in the healing of certain of these chronic undermining ulcers. The ease of administration of this drug further simplifies the treatment. The only necessary laboratory studies are periodic blood counts. Blood sulfanilamide determinations may be performed if desired. Wound cultures are important in evaluation of results.

In this paper a successful outcome in the case of one of these ulcers from the administration of

sulfanilamide is described. Approximately 8400 gr of sulfanilamide was given over a period of three months without more than a slight transient effect on the bone marrow and on liver and kidney function.

CASE REPORT

M. D., a 15-year-old school girl was admitted to the Surgical Service at the Massachusetts Memorial Hospitals on August 17, 1938. Two and a half months previously she had sustained a floor burn in the school gymnasium, the affected area being just below the knee on the anterolateral aspect of the left leg. Iodine was applied by the patient, but a moderate degree of infection developed. She was then treated in a clinic and ammoniated mercury ointment dressings were used during a 2 week period. There was progression of the lesion despite this treatment, an ulcer with undermined edges and a central sinus being formed. Surrounding acute cellulitis required wet dressings for a few days. Incision and drainage of the central sinus was done on June 18. Within a week, an exacerbation of the acute cellulitis occurred requiring hospitalization for several days. During the following 6-week period—prior to admission at the Massachusetts Memorial Hospitals—the ulcer remained in an indolent state, not improving with ointments and other local treatments. The patient walked with difficulty owing to pain on moving the knee. There was little spontaneous pain in the ulcer. Her general health was not impaired. The past history was negative except for an intermittently running ear of several years duration.

Physical examination revealed a well-developed and well-nourished girl. The color was good. There was a moderate degree of acne vulgaris. Systemic examination was generally negative aside from the left lower extremity. On the anterolateral aspect of the left leg was a roughly ovoid ulcer 9.0 by 7.0 by 0.8 cm. its upper margin being just below the head of the fibula. It extended part way onto the calf laterally where the bed of the ulcer was apparently formed by the aponeurosis of the soleus muscle. Soft granulations with a moderate degree of infection lined the open bed. The lateral margin was deeply undermined and draining thin yellow gray pus, with a slightly musty odor. There was shallow undermining in two places along the superior and medial margins of the ulcer. The surrounding skin for a distance of 3 to 6 cm showed a scaling eczematoid lesion. Motion was free in the joints of this extremity. Muscle function seemed

*From the Department of Surgery, Massachusetts Memorial Hospitals, Boston.

†Resident in surgery, Ford W. Hospital, Wrentham, Massachusetts; formerly surgical resident, Massachusetts Memorial Hospitals, Boston.

normal, although there was slight atrophy of disuse. No regional lymphadenopathy was found.

Urinalysis was entirely negative. The blood nonprotein nitrogen was 27 mg per 100 cc., and the blood sugar 111 mg. The Wassermann and Kahn tests were negative. The white-cell count was 10,700, with 75 per cent polymorphonuclear leukocytes, 23 per cent lymphocytes and 2 per cent endothelials. The hemoglobin was 78 per cent, and the red-cell count 4,450,000. X-ray films of the knee region revealed only bone atrophy.

The day after admission, under nitrous oxide and ether anesthesia, the sinuses at the ulcer margins were laid open and the infected granulations were curetted out. Cultures from this material showed an aerobic hemolytic streptococcus, *Staphylococcus aureus* and *Staph albus*. No anaerobic or microaerophilic organisms were identified. Examination of smears failed to demonstrate fungi, yeasts or tubercle bacilli. The pathologist's report on sections of this material was "acute and chronic inflammation, granulation tissue."

Under the influence of wet saline and Dakin's solution dressings, during the next 2-week period the ulcer bed became cleaner, but did not decrease in size. The surrounding skin was somewhat macerated. The culture results continued to be the same, although but few organisms were found in the smears.

On September 12, 1 month after admission, dressings of active zinc peroxide paste were instituted according to the technic of Meleney.² The granulations became clean and solid, and healthy epithelium began to grow in from the margins. Progress was so favorable that the area was pinch-grafted on September 19, the zinc peroxide being continued with only a 24 hour interruption. After an 8-day period the grafts became liquefied. There was an exacerbation of the infection in the ulcer bed. The granulations were gelatinous and purple-gray, and exuded an excess of thin, gray pus with a musty odor. Cultures taken at this time yielded *Bacillus pyocyaneus*, in addition to a hemolytic streptococcus and *Staph aureus*. Technical difficulties were then encountered in the use of the zinc peroxide. The material obtainable was very low in nascent-oxygen production (by Meleney's test-tube determination). Either because of this factor or because of the presence of the new organism, the zinc peroxide proved ineffective. Dressings moistened with 2 per cent acetic acid were used for several days, with definite improvement, and by the end of September the ulcer had decreased to roughly 4 cm. in diameter. The bed was shallow. In the next 2 weeks, however, a relapse occurred, the area becoming larger despite resumption of both acetic acid and zinc peroxide dressings for adequate treatment periods. *B. pyocyaneus* continued to be present in cultures for the next 6 weeks.

X-ray therapy (344r in seven treatments—200 kv, unfiltered) was given over a period of 10 days. For control purposes saline dressings only were used locally. The response to the x-ray treatment was unfavorable, the ulcer becoming larger during this period (Fig 1). On October 19, the patient was started on sulfanilamide therapy, given with appropriate amounts of sodium bicarbonate by mouth. This was continued with the dosage ranging from 80 to 100 gr daily in divided doses until the middle of January, 1939. During that time the ulcer healed in gradually, the response to the sulfanilamide being very convincing, and certainly more consistent than that to any of the other treatments used. It was necessary to discontinue the drug for a number of days on several occasions because of the destructive effect on the red blood cells, which fell as low as 2,600,000 per cubic millimeter.

Four transfusions were given, the first on December 19, with a satisfactory resultant rise in the red-cell count. The white cells were not affected, and the patient had no constitutional reaction of significance. Mild cyanosis was observed at times, and moderate anorexia occurred when

FIGURE 1 The Ulcer at the Start of Sulfanilamide Treatment—October 21, 1938

large doses were being given. On several occasions during the enforced rest period from sulfanilamide minor exacerbations of the ulcer activity occurred, the change from the infected, malignant-appearing, spreading, purple gray granulations present at such a time to a relatively clean ulcer, within 48 hours after resumption of the sulfanilamide, was quite dramatic. The sulfanilamide level, taken frequently during this period, ranged from 0.5 to

FIGURE 2 The Ulcer in an Advanced Stage of Healing after Three Months of Sulfanilamide Treatment—January 16, 1939

34 mg per 100 cc, being generally proportional to the dosage and the healing effect.

The majority of the pinch grafts planted November 26, during the course of sulfanilamide treatment, took, and acted as foci from which epithelium spread over the ulcer. Small doses of sulfanilamide (40 gr daily) were effective during January and February, but when the drug was entirely omitted exacerbation of the ulcer took place (Fig 2). By February 25 only two tiny granulating

points remained, and it seemed feasible to discontinue the sulfanilamide. A total of 8400 gr had been given. Cultures showed only *Staph aureus*. The eczematoid reaction of the surrounding skin persisted for some time thereafter, but the ulcer was entirely healed by the time of discharge, in March 1939. The function of the leg was normal. The patient's general health was excellent. The peripheral blood picture was normal.

The patient returned to the hospital 3 months later for a general check-up. At that time the skin over the previous ulcer area was solid although still somewhat thin. There was moderate fibrosis of the subcutaneous tissues. The leg function was normal. Tests of kidney and liver function were within normal limits.

COMMENT

The ulcer described above stubbornly resisted various forms of treatment for two months. Dakin's

After the initial treatment period of two months, the ulcer was only a little smaller than on admission. There was less undermining, but the granulations of the base were still heavily infected. Sulfanilamide treatment begun at that time gained control of the inflammatory process within four days. Epithelialization, however, was slow. Through their experiments with dogs, Bricker and Graham⁹ have shown that sulfanilamide exerts some inhibitory effect on wound healing. This may well be true in clinical practice also. The periods of rest from the sulfanilamide, necessitated by significant drops in the red-cell count, also added to the total healing time. Resumption of the drug on each occasion demonstrated convincingly its prompt effect on the inflammatory process.

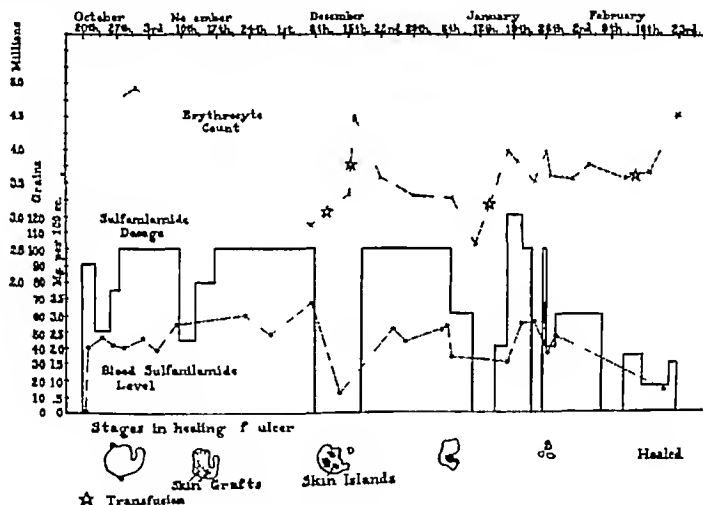

FIGURE 3 Sulfanilamide Dosage in Relation to Erythrocyte Levels

solution, simple saline dressings and dilute acetic acid all seemed effective in cleaning up the lesion at times, even promoting a degree of healing. Exacerbation of the ulcer activity then invariably occurred. Zinc peroxide at first appeared even more effective. When however, an attempt was made to punch-graft the clean ulcer base, the grafts promptly sloughed and the ulcer again became active. Zinc peroxide paste was ineffective when tried on three subsequent occasions. This failure may well have been due to the inferior oxygen liberating power of the material available. The complicating organism, *B. pyocyaneus* present in the ulcer at this time may also have had some influence. X ray therapy was entirely ineffective

It is rarely necessary to administer sulfanilamide in such high total dosage (8400 gr) for so prolonged a period (four months). When one recalls the great interest shown in toxic side effects of this drug during recent months,¹⁰ this case is of some importance in indicating the quantities which can be administered safely to a nonsusceptible individual. Moderate reduction in the red cell count and a slightly diminished renal function during the treatment period were the only significant toxic effects. Three months later a check up of the peripheral blood picture and the renal and hepatic functions by standard methods showed normal findings.

Despite daily dosages of 100 gr of sulfanilamide

for long periods, it was never possible to raise the blood serum level above 3.4 mg per 100 cc. The low serum sulfanilamide level may have accounted in part for the absence of serious side effects.

Approximately 60 gr of sulfanilamide daily was required to maintain the ulcer in a healing phase, with a dosage of 80 to 100 gr (2 or 3 mg per 100 cc serum level) as a safe margin. This affords an interesting comparison with Goodman's⁸ findings. In his 2 ulcer cases, which were similar to that described herein, daily sulfanilamide dosage of 40 to 60 gr was adequate to promote healing. Daily dosage of 120 gr for a short period in our case resulted in no additional improvement in the healing and gave the patient anorexia and mild cyanosis. There was no febrile reaction on resumption of the sulfanilamide in full doses after a rest period, or at any other time. The patient experienced no reaction after any of the four transfusions, nor was there any ill effect from simultaneous administration of ferrous sulfate and the sulfanilamide, over fairly long periods.

Figure 3 illustrates the course of the sulfanilamide administration, together with the levels of the blood sulfanilamide obtained and the effect on the erythrocyte count. The leukocyte count ranged between 6000 and 16,000. Since it did not seem significantly influenced by the sulfanilamide, it is not shown in the graph.

No microaerophilic hemolytic streptococci were recovered from this ulcer. The strain was beta hemolytic and seemed to grow well in air. In one culture a poor growth of *Str. viridans* was identified, after periods of both zinc peroxide and sulfanilamide treatment. Clinically, however, the ulcer resembled the type described so adequately by Meleney and from which he was able to isolate

microaerophilic organisms. The admittedly good control of the ulcer activity obtained by the first and potent lot of zinc peroxide seems to justify further the classification of this ulcer with Meleney's group.

A combination of zinc peroxide dressings—when a more constantly potent product can be developed—and sulfanilamide, administered systemically, may well prove the ideal treatment for this serious disease.

SUMMARY

The healing of a resistant, chronic, undermining streptococcal ulcer following the administration of sulfanilamide is reported.

The salient features of this case were the prompt and convincing subsidence of the inflammatory process and institution of healing in the ulcer from the use of sulfanilamide, in contrast with other methods of treatment, and the absence of any but transitory and mild toxic effects from the administration of 8400 gr of sulfanilamide during a period of four months.

CLINICAL SIGNIFICANCE OF ORAL LESIONS IN
ACUTE LEUKEMIA

WILLIAM C. MOLONEY, M.D.*

BOSTON

THE recognition of the importance of mouth lesions in various systemic disorders is of comparative recent date. Among others, Marshall and Lucia¹ have emphasized that many diseases of the blood present their most important signs and symptoms in the mouth. Love found that 82 out of 152 cases of various types of leukemia showed oral lesions, and Musser² states that in acute leukemia oral lesions are usually present. A study of blood dyscrasias in the past four years has amply borne out these statements.

Leukemic manifestations in the mouth are mainly confined to the gingival tissues and mucous membranes. The commonest lesion is bleed-

Clinically, oral lesions in acute leukemia are important not only because they occur in a large percentage of cases, but also because very frequently they are the earliest sign of the disease. Of the 9 patients of this group with oral signs, 7 first visited the doctor or dentist because of bleeding from the gums, trench mouth or pain in the jaw. The following cases illustrate this.

CASE 1 J. C., a 23-year-old man, complained of a sore mouth, pain in the teeth and swollen bleeding gums. He was treated by a dentist for "trench mouth" and his mouth improved. However 3 months later his gums again bothered him and in addition he developed anorexia, became tired easily and felt run down. Because of weakness and loss of weight he was admitted to the Carney Hospital 7 months after the onset of his sore mouth.

Physical examination revealed an acutely ill man. His gums were swollen and pale, but there was no ulceration or evidence of petechial hemorrhage. There was a murmur at the cardiac apex, but no other findings in the heart and lungs. The liver and spleen could not be felt, nor were there any palpable lymph glands. The red-cell count was 1,650,000 the white-cell count 17,200 and the hemoglobin 35 per cent (Sahli). A stained smear revealed markedly diminished platelets, anisocytosis and poikilocytosis. A differential count showed 12 per cent lymphocytes, 10 per cent adult polymorphonuclears, 39 per cent band forms, 30 per cent myelocytes and 9 per cent myeloblasts. A diagnosis of myelogenous leukemia was made. The patient went steadily downhill and died 2 months after admission.

CASE 2 C. McP., a 30-year-old man visited his physician for treatment of a badly infected mouth. The gums were bluish-black, and there was a foul exudate over the mucous membranes. The mouth under conservative treatment improved considerably. However the patient's general condition became worse and he developed generalized edema marked pallor weakness and fever. One month after the mouth lesion developed he was confined to bed. Blood studies made at this time showed a hemoglobin of 15 per cent (Sahli) a red-cell count of 1,550,000 and a white-cell count of 58,600. A differential count showed the cells to consist almost entirely of myelocytes and myeloblasts very few platelets were present. The red cells showed marked variations in size and shape, and many were nucleated. At this time the gums were very pale but were otherwise free of infection or bleeding. Throughout the illness there were no enlarged lymph nodes and neither the spleen nor the liver was palpable. One week after the blood study revealed the underlying disease the patient died.

As pointed out by Forkner³ and others gangrenous stomatitis is especially prone to occur in acute monocytic leukemia. Forkner states "In acute monocytic leukemia, diffuse swelling of the gingivae with a tendency for the teeth to become submerged in the gums is encountered in the

TABLE 1 Oral Lesions in Cases of Leukemia

| CASE No. | SEX | AGE | DIAGNOSIS | ORAL LESIONS |
|----------|-----|-----|-------------------------------|--|
| 1 | M | 23 | Subacute myelogenous leukemia | Gingivitis; bleeding from gums |
| 2 | M | 30 | Acute myelogenous leukemia | Ulcerath stomatitis |
| 3 | F | 58 | Acute monocytic leukemia | Ulcerath stomatitis |
| 4 | F | 50 | Acute monocytic leukemia | Ulcerath stomatitis |
| 5 | M | 39 | Acute myelogenous leukemia | Gingivitis; pain in jaw |
| 6 | F | 38 | Acute lymphatic leukemia | Pain in the jaw and bleeding from gums |
| 7 | M | 52 | Acute myelogenous leukemia | Bleeding from gums |
| 8 | M | 17 | Acute myelogenous leukemia | Bleeding from gums |
| 9 | F | 11 | Subacute myelogenous leukemia | Bleeding from gums |
| 10 | F | 5 | Acute lymphatic leukemia | No oral lesion |
| 11 | M | 15 | Acute myelogenous leukemia | No oral lesion |
| 12 | F | 62 | Acute monocytic leukemia | No oral lesion |

ing from the gums, the mechanism of which is not fully understood. Probably it is due in part to infiltration of the bone marrow by leukemic cells, which crowd out or inhibit the megakaryocytes with a resulting platelet deficiency. Subsequently secondary infection and ulceration may occur, or injudicious surgical procedure may result in necrosis and gangrenous stomatitis.

Infiltration of the gums by leukemic cells occurs in acute leukemia. This results in swollen gums, which are painful and bleed easily on slight trauma. At times this swelling is so extreme that the gums cover the teeth. Ulceration and necrosis occur very frequently.

In the series presented here (Table 1) the patients with leukemia had bleeding, pain or infection of the gums, with or without ulcerative stomatitis.

*Instructor in medicine, Tufts College Medical School; director of Blood Clinic and associate visiting physician, Carney Hospital, Boston.

great majority of cases." He believes that the oral lesions in acute lymphatic and acute myelogenous leukemia are usually nonspecific. Osgood⁵ reviewed cases of monocytic leukemia, and reported that gingival swelling was noted in 80 per cent of 88 cases in which the gums were mentioned. Not all investigators agree with Forkner that the infiltrative lesion is almost always pathognomonic of acute monocytic leukemia, but in general it is well recognized that gingival involvement is frequent in acute leukemia.

In the present series there were 3 cases of acute monocytic leukemia, and in 2 of them (Cases 3 and 4) extensive necrotic and ulcerative lesions developed from what at first appeared to be "trench mouth." The mere presence of Vincent's organisms and other secondary bacterial invaders should not lead to this diagnosis, as it implies a purely local process. In both cases mentioned, patients first visited the dentist, but the progressive character of the gingival lesions, with the rapid onset of pallor, fever and prostration, led to further investigation and the discovery of the background of acute leukemia.

Not infrequently cases have been reported illustrating the disastrous results of tooth extraction or other oral surgery. Recently Klumpp and Evans⁶ in a paper recording 8 cases of monocytic leukemia stated that 5 of these were discovered following extraction of teeth. In this regard the following 3 cases are of interest.

CASE 5 R. P., a 39-year-old man, visited a dentist because of pyorrhea, bleeding gums and pain in the lower jaw. His lower incisors and bicusps were removed, and 1 week later he was admitted to the Carney Hospital with extensive gangrene of the mouth. The hemoglobin was 48 per cent (Sahli), the red-cell count 2,600,000 and the white-cell count 69,000. The stained smear showed cells which appeared to be stem cells of the myeloid group. The patient died 48 hours after admission. Autopsy confirmed the diagnosis of acute myelogenous leukemia.

CASE 6 C. D., a 38-year-old woman, went to the dentist because of pain in the jaw. No local lesions which would account for this pain were found, but the patient insisted that the teeth be removed. Subsequent to the extraction she bled profusely from the sockets and then developed generalized oozing from the gums. Because of weakness, fever and severe epistaxis she entered St. Elizabeth's Hospital several weeks later. The laboratory findings were as follows: hemoglobin 20 per cent (Sahli), red-cell count 1,400,000 and white-cell count 1200. The stained smear showed markedly reduced platelets with white cells which were entirely of the lymphocyte group. Most of these were adult lymphocytes, but several lymphoblasts were found, and a diagnosis of acute lymphatic leukemia was made. Bone marrow biopsy substantiated this diagnosis, and soon afterward the patient died.

CASE 7 S. K., a 52-year-old man, had a molar extracted from his upper jaw and developed pain and bleeding at the site of extraction. The gum failed to heal, and he developed weakness, general malaise and aching pains in

the gums. When admitted to the Somerville Hospital 1 month later he had diffuse ulceration and pyorrhea of the gums, with necrotic material in the unhealed socket. Otherwise the physical examination was essentially negative. The laboratory findings were as follows: hemoglobin 38 per cent (Sahli), red-cell count 1,820,000 and white-cell count 2750. The stained smear showed 2 per cent adult polymorphonuclear leukocytes, the remainder of the cells looked like large lymphocytes, but an oxidase stain identified them as promyelocytes, and bone marrow biopsy substantiated the clinical diagnosis of myelogenous leukemia. This patient left the hospital. He died about six months later.

In the remaining 5 cases there was bleeding from the gums in 2 (Cases 8 and 9), and no oral lesions in the other 3. In Case 8 retinal hemorrhage with blindness was the initial and outstanding manifestation, although severe bleeding from the gums also occurred early in the course of the disease. Jaundice, enlarged liver and spleen and an aleukemic blood picture featured the course of Case 9. The patient developed bleeding from the gums, but this disappeared with the jaundice. For several months she was practically free of symptoms, but she finally succumbed after developing a blood picture typical of myelogenous leukemia.

DISCUSSION

Physicians and dentists should be encouraged not to regard the oral cavity as an entity, but rather to consider that the mouth has often the same relation to the body as have the eyegrounds, and frequently will be found to reflect underlying systemic disorders. Whenever they are confronted with apparently benign bleeding or gingivitis they should not fail to inquire into all the possibilities. Locally, pallor, ulceration and petechial hemorrhages of the mucous membranes, tonsillar enlargement and the presence or absence of glandular swelling in the neck should be noted. The prognosis should be guarded when there is severe stomatitis, especially in a patient with fever, pallor and dependent edema.

Acute leukemia is not a common disorder, and there are many diseases that may have oral manifestations of a similar type. In many cases a diagnosis by local investigation alone is impossible. Severe sepsis, agranulocytosis, infectious mononucleosis, essential purpura, hemophilia, scurvy, aplastic or myelophthytic anemias and rarely pernicious anemia may give rise to serious diagnostic difficulties, especially in the differentiation from aleukemic and leukopenic leukemias. Both the clinical course and routine blood studies in these atypical leukemias may be misleading, in any event the patient must be given the benefit of the doubt, and specific therapy, when possible, administered as early as compatible with good clinical judgment. On the other hand, indiscriminate

therapy before a diagnosis has been established should be deplored. Every reasonable clinical and laboratory test necessary for diagnosis should be applied before blood transfusion, Pentnucleotide, liver extract and chemotherapy have so confused the situation that a true picture of the case is impossible.

CONCLUSIONS

Oral lesions are frequent in acute leukemia, and are prone to occur early in the course of the disease.

Accurate diagnosis is important, in order that those conditions which simulate certain types of

leukemia may be differentiated and early therapy be instituted

It is evident that acute leukemia is an invariably fatal disease, but palliative measures and the avoidance of injudicious oral surgery will make the sufferer much more comfortable

ONE-STAGE LOBECTOMY IN BRONCHIECTASIS*

M. DAWSON TYSON, M.D.†

HANOVER, NEW HAMPSHIRE

THE historical aspect of the development of pneumonectomy and lobectomy in man has been presented by numerous authors, notably Balloon, Singer and Graham,¹ Haight² and Heuer.³ Dissatisfaction with the one stage lobectomy for bronchiectasis early in the century was materially lessened by the development of the multiple stage attack, together with the perfection of anesthesia, the employment of new diagnostic methods and the better understanding of thoracic physiology. All these improvements rendered more feasible the approach to the ideal operation, namely a reasonably safe one stage procedure. A turning point in this direction came with the work of Brunn,⁴ published in 1929, at which time he reported 6 one-stage lobectomies with 1 death. In 1933 Alexander⁵ presented a two-stage procedure with a mortality below 20 per cent. The first stage consisted of creating adhesions between the healthy lobes and the chest wall so as to reduce the size of the pleural cavity and stabilize the mediastinum. In a review published in 1934, Heuer⁶ stated that the two-stage procedure still had the lowest individual mortality, although he predicted that the one-stage operation would become more frequent. Churchill⁷ in 1936 reported a mortality of 6 per cent in 49 cases covering the years 1929 to 1935. In 18 cases the one stage procedure was employed. At present it is probably true that most surgeons prefer the one stage method, but reserve the multiple stage attack for certain cases.

This article reports 5 cases of unilobar bronchiectasis in which lobectomy was performed in one stage. These cases represent all the one stage lobectomies performed at the Hitchcock Clinic for simple unilobar bronchiectasis, and in this group there has been no mortality. Lobectomy in cases with bilateral disease, tumor and tuberculosis is not considered at this time.

All cases were fully investigated for the presence of tuberculosis. Particular attention was paid to even moderate degrees of secondary anemia, which was present in 3 cases. All patients were bronchoscoped prior to operation. Postural drainage was instituted routinely, and close supervision was given in order to ensure favorable results. Adequate time was allowed to get the patient in the best possible condition for operation.

Intravenous saline and glucose were started just before operation by tying a cannula in an ankle vein. Avertin was administered on the 80-mg scale, and nitrous oxide and ether were introduced through the Flagg type of intratracheal tube. In the lower lobe cases the seventh rib was resected in the posterolateral aspect. In the upper lobe case the incision was made through the bed of the sixth rib. The Bethune modification of the Shenn stone tourniquet was employed at the hilus. Closure of the hilar stump was obtained by mattress sutures of catgut.

Drainage was employed in 4 cases. In Case 2 (upper lobe) no drainage was employed, and empyema resulted. In 3 cases drainage was done by means of a No. 24 urethral catheter inserted posteriorly just above the diaphragm, moderate

*Presented at the annual meeting of the New England Surgical Society, Boston, Massachusetts, September 30, 1939. From the Hitchcock Clinic, Hanover, New Hampshire.

†Member of the Department of Surgery, Mary Hitchcock Memorial Hospital, Hanover, New Hampshire.

suction being applied at the bedside. In Cases 4 and 5, in addition to the posterior catheter, a Pezzar catheter was inserted anteriorly, and 6 to 8 cm of water suction was applied to both tubes. Re-expansion of the lung was greatly facilitated by this procedure. In these 2 cases bronchoscopic aspiration of the tracheobronchial tree was carried out immediately at the close of the operation. It resulted in marked improvement in the oxygenization and comfort of the patient in the first postoperative hours. All 5 patients were given a transfusion of citrated blood during or immediately after operation. The oxygen tent was employed routinely, but only for a few hours in Cases 4 and 5.

In Case 1, mild hemoptysis occurred a year after lobectomy. This was successfully treated by bronchoscopic cauterization of the left lower lobe stump. There has been no recurrence in two years. In Case 2, a hemolytic streptococcus empyema occurred, which was successfully treated with Pron-tosil. However the cavity left by lobectomy failed to close, and the empyema recurred a year after operation. This was treated by thoracostomy, followed by a regional thoracoplasty for closure of the cavity. There has been no further trouble in a year and a half. In Case 3, a mild wound infection developed but cleared promptly with drainage. In Cases 4 and 5 there were no complications.

All the patients were free of cough and sputum and were able to carry on their normal occupations. In Case 1 a postoperative Lipiodol injection showed a slight saccular end of the bronchial stump at the point of amputation. The patient was entirely well, however, and has been through two winters without trouble.

CASE REPORTS

CASE 1 C M, a 32-year-old, married woman, was admitted July 15, 1936. Except for an attack of pneumonia in childhood, she had been in perfect health until 3 years before admission, when she had a small hemoptysis. At that time the hemorrhage was considered to have come from the nose or throat, and although the lungs were examined with a stethoscope no x-ray film was taken, and the patient was considered well. One year before admission, while sitting quietly in a chair, she had a second hemoptysis of a mouthful of blood. An x-ray film was negative, and a tuberculin test also was negative. Repeated sputum examinations failed to show tubercle bacilli. Five weeks before admission she had a severe pulmonary hemorrhage, the blood spurting from her mouth, and she lost nearly a quart of blood. Again sputum examination and a tuberculin test failed to indicate any disease process.

Physical examination on admission showed a rather pale, sallow, undernourished woman in a nervous condition. The entire examination was negative. The red-cell count was 3,700,000, and the white-cell count 5800. Urinalysis

was negative, and sputum tests for tuberculosis also were negative. Plain x-ray films of the chest were negative, except for an old healed tuberculous infection of the right hilus nodes. Bronchoscopic examination was negative. Lipiodol injection showed bronchiectasis of the medial bronchi of the left lower lobe, with some atelectasis and failure of alveolar filling (Fig 1).

On July 30, under intratracheal anesthesia, a posterolateral incision was made, and it was found that the lower lobe was densely adherent to the diaphragm by vascular adhesions. There was an incomplete separation between the upper and lower lobes, so that the tourniquet was applied to the lower lobe and the base of the upper. The stump of the lower lobe was secured with mattress sutures. There were no adhesions between the upper lobe and the chest wall. A No. 24 urethral catheter was

FIGURE 1 Case 1
Atrophic bronchiectasis of the left lower lobe, with atelectasis

inserted through a trocar wound in the posterolateral aspect of the chest just above the diaphragm, and the wound was closed in layers. Moderate suction was placed on the catheter as soon as the patient had been returned to the ward. The pathological diagnosis was atrophic bronchiectasis and chronic pneumonitis.

In the first 48 hours after operation some difficulty in raising sputum was encountered, but this was lessened by postural drainage, the patient coughed up some blood-streaked mucus. The drainage tube was removed on the 8th postoperative day. The temperature rose as high as 101°F on each of the first 5 postoperative days. It then gradually declined to normal. The patient was discharged on the 27th postoperative day. An x-ray film taken at discharge showed that the left lung was completely expanded. The lung fields were clear except for the remains of Lipiodol at the right base. The heart was displaced slightly to the left.

On December 28, 1937, the patient had another small hemoptysis. She was readmitted to the hospital, and bronchoscopic examination showed an area of granulation tissue in the bronchial stump of the left lower lobe. This was cauterized, and for the last 2 years the patient has

been perfectly well and has gained weight. She has had no cough or sputum and no complaints.

Case 2. R. L., an 18-year-old girl, was admitted on January 25, 1937 complaining of persistent cough productive of foul smelling sputum, amounting sometimes to 100 or 150 cc. a day. She had had several attacks of pneumonia in childhood each one leaving her with more cough. Five years before admission the sputum increased in amount and became foul-smelling. There was an occasional frank hemoptysis. The patient could not take part

FIGURE 2. Case 2

Appearance of the cyst on admission to the hospital. Note the fluid level and the small amount of Lipiodol in bottom of the cyst.

in social activities because of the frequency of the cough and the foulness of the sputum. Routine x-ray films taken at school 1 month before admission showed a lesion in the right upper chest. The patient was sent to another hospital, where a Lipiodol injection was done. Following this examination she became very ill, with fever, sweat, and weight loss. The sputum increased to 250 or 300 cc. a day and she was unable to lie down for fear of choking.

Physical examination showed a sallow-complexioned girl, fairly well nourished and not acutely ill. There was a frequent cough productive of foul sputum. The patient was unable to lie flat in bed because of the cough. Examination of the chest revealed impaired resonance and decreased aeration of the right upper lobe. There was marked clubbing of the fingers. The temperature was 99.8 F. The red-cell count was 4,310,000 and the hemoglobin 13 gm. There were 12,500 white cells, with 57 per cent polymorphonuclears and 27 per cent lymphocytes. The urine showed 0.007 gm. of albumin; otherwise the examination was negative. Examination of the sputum showed no spirochetes, a few pneumococci and numerous streptococci. Repeated examinations failed to show tubercle bacilli. An x-ray film of the chest showed a large, round cavity 8 cm. in diameter in the mid-portion of the right lung (Fig. 2). The cavity was half filled with fluid, with a small amount of Lipiodol at the bottom.

The wall was extremely thin and there was no reaction in the surrounding lung. The medial wall of the cavity was in contact with the mediastinum; in the lateral view the anterior wall was in contact with the anterior wall of the chest, the loculation being in the lower portion of the upper lobe. The lung fields were otherwise clear. The x-ray diagnosis was congenital lung cyst with bronchial communication. The patient improved remarkably on postural drainage. She received three injections of neoarsphenamine. On February 28 days after admission an x-ray film showed that the upper lobe cyst had been emptied of its contents. The temperature at this time was normal and lobectomy was advised.

The right upper lobe was removed on February 16. A posterolateral incision was made, with resection of the sixth rib. The pleural space over the upper lobe was completely obliterated by rather dense adhesions, some of which were quite vascular. The lower and middle lobes were also adherent to the chest wall. A segment of the seventh rib was also resected to improve the exposure, and the lobe was dissected away from the chest wall and mediastinum. It was seen that the cyst in the anterior surface of the upper lobe was provided with a separate

FIGURE 3. Case 2.

Surgical specimen showing the cyst and the atelectatic upper lobe.

bronchus arising from the right upper lobe bronchus. Tourniquets were placed about the hilus of the latter and the lobe was amputated. The stump was secured with mattress sutures, and the chest was closed without drainage (Fig. 3). The pathological diagnosis was bronchial cyst, congenital. It is possible that the cyst could have been dissected away without complete removal of the lobe, but it was thought to be too deeply imbedded.

The patient reacted very well after the operation. The

temperature rose to 101°F the next day, and on the following day to 102. Thoracentesis on the 7th day yielded fluid which gave a pure culture of hemolytic streptococci. The infection was treated by injecting Protosil into the cavity and also intramuscularly. On the 21st postoperative day the chest fluid was sterile, and from then on the course was one of rapid improvement, the temperature returning to normal. The patient was discharged on the 33rd postoperative day, at which time she had no cough or sputum. It was noteworthy, however, that the mid-

of 5 she had a second attack of pneumonia, following which the sputum gradually increased. There were several other attacks of pneumonia, the last occurring in March, 1937. The patient was practically never without a "cold." Her general health was good. She was able to enjoy mild exercise and gained steadily in general development.

Physical examination showed a well developed and nourished girl in no acute distress. The only positive findings were in the thorax, where the expansion of the left chest was greatly reduced and that of the right was exaggerated. Tactile fremitus and whispered voice were markedly increased over the left base posteriorly, and there were scattered moist rales over this area. There was structural scoliosis with convexity to the right. The red cells numbered 4,120,000 and the white cells 8300, the hemoglobin was 13.5 gm. X ray examination showed the left side of the thorax to be considerably smaller than the right, with corresponding scoliosis of the thoracic spine. The entire lower half of the left lung field was obscured by homogeneous density. The upper portion of the lung appeared clear. The appearance was that of atelectasis of the left lower lobe. Lipiodol injection showed that there was a marked saccular bronchiectasis involving the entire left lower lobe, with marked atelectasis in this region.

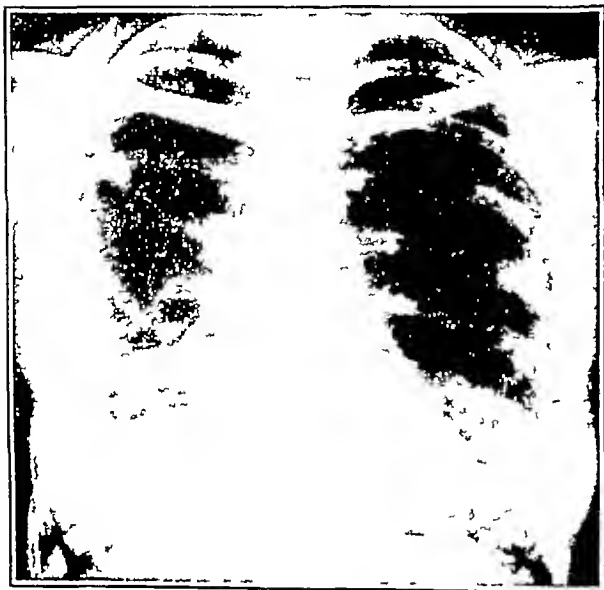

FIGURE 4 Case 2

Cavity left after lobectomy due to failure of the lower and middle lobes to overexpand

dle and lower lobes never overexpanded so as to occupy the space created by removal of the upper lobe (Fig 4).

The patient remained well through the next year, without cough or sputum. She was readmitted, however, on January 22, 1938, with fever and pain in the right chest. The temperature rose to 104°F each day, and the patient was obviously toxic. X ray examination showed an accumulation of fluid in the space previously occupied by the upper lobe. The red-cell count was 4,000,000, and the white-cell count 11,700. Thoracentesis in this region resulted in the recovery of thick, green pus, which on culture showed non hemolytic streptococci and pneumococci. Blood culture was sterile. It was considered that the bronchial stump must have opened and that the pleural cavity had become contaminated through this avenue. An incision at the anterior edge of the old lobectomy scar was made, and large quantities of pus were evacuated. The temperature immediately dropped to normal and remained there, and 21 days later a thoracoplasty was performed with resection of the first five ribs. The patient recovered rapidly from this procedure, obtained a good collapse of the cavity and returned home 16 days after the last operation. She has remained well during the year and a half following the last operation.

CASE 3 A. L., a 15-year-old girl, was admitted August 25, 1937. She gave a history of always having had "chest trouble." Since an attack of pneumonia at the age of 2 she had had a chronic cough with production of about 30 cc. of thick, yellow sputum a day. At the age

FIGURE 5 Case 3

Advanced saccular bronchiectasis of the left lower lobe, with atelectasis of the lobe and compensatory changes in the right lung. The scoliosis was probably due to atelectasis with pleural adhesions.

There was overexpansion of the right lung field, which extended a third of the way into the left thorax. This was considered to be a typical surgical case (Fig 5).

Lobectomy of the left lower lobe was performed on November 10. The usual posterolateral incision was made. The left lower lobe was found to be dark red, firm and atelectatic. It was densely adherent to the chest wall, diaphragm and upper lobe. The base of the upper lobe was adherent to the chest wall. After lobectomy in the usual manner a No. 24 urethral catheter was inserted just above the diaphragm in the posterolateral aspect of the chest.

The pathological diagnosis was hypertrophic bronchiectasis, with marked chronic interstitial pneumonitis and fibrosis.

Immediately after the operation the patient ran a fever which reached 102 F on the 3rd day. This was found to be due to a wound infection and when the latter was drained the temperature returned abruptly to normal. Convalescence was uneventful. The patient was discharged on the 39th postoperative day without cough or sputum.

The patient has been seen repeatedly in the follow-up clinic and has remained well. She goes through the winter with one cold and has no cough or sputum. There is considerable shift of the heart to the left, occupying the region of the lower lobe. The scoliosis is not improved.

Case 4 E. T., a 31 year-old woman was admitted July 10, 1938. She had had eight hospital admissions elsewhere, mostly for pelvic operations. In 1933 she was badly

FIGURE 6. Case 4

Moderate saccular bronchiectasis of the right lower lobe

injured in an automobile accident, and was unconscious for several days. Her chief complaint at the time of admission was a productive cough since February 1937 with frequent hemoptysis. There was frequent joint pain and weakness and fatigue during this time.

Physical examination was essentially negative, except for reduced aeration of the right lower lobe with occasional rales. The red-cell count was 4,900,000 and the white-cell count 6000. The hemoglobin was 16 gm. Repeated examination of the sputum was negative for tubercle bacilli. A tuberculin test was negative. At x-ray examination the lung markings at the right base were increased in width and density. In the lateral view these markings lay in the region of the lower lobe. Otherwise the lung fields were clear. Lipiodol injection showed saccular bronchiectasis of the lower lobe bronchi associated with failure of alveolar filling (Fig. 6). The rest of the bronchi were normal. The patient returned home for some days and was readmitted on August 15.

At operation September 26 the lower lobe of the right lung was found densely adherent to the lateral chest wall. The base of the upper lobe was also connected to the chest wall by a few delicate strands. The fissure between the

lobes was incomplete. The lower lobe was amputated in the usual manner. For drainage a No. 24 urethral catheter was inserted posteriorly and a No. 24 Pezzer catheter anteriorly. After closure of the chest, suction was placed on both catheters. At the end of the operation a bronchoscope was passed and the tracheobronchial tree was cleaned of secretions. The pathological diagnosis was chronic bronchiectasis.

The patient had an entirely uneventful postoperative course. The temperature reached 101 F on the 3rd postoperative day but rapidly declined to normal thereafter. X-ray examination of the chest the day after operation showed the right lung nearly completely expanded and practically no fluid present in the pleural cavity. The patient was sent home on the 21st postoperative day having gained 4 pounds in the first 2 weeks following operation.

The patient has been free of cough and sputum, although she has had complaints referable to other parts of the body.

Case 5 L. F., a 26-year-old man was admitted May 1 1939. He had had pneumonia at the ages of 15 16 and 17. Five years previously he had developed a productive cough which had been present ever since. He raised

FIGURE 7. Case 5

Moderate bronchiectasis of the right lower lobe

large quantities of foul sputum and was practically never without a "cold."

Physical examination was essentially negative except for decreased aeration and scattered rales over the right lower lobe. The red-cell count was 4,650,000 and the white-cell count 17,050. Urinalysis was negative. Repeated examinations of sputum were negative for tubercle bacilli. Serological tests were negative. X-ray examination showed an increased density of the lower portion of the right hilus and of the lung markings running to the cardiophrenic angle. Otherwise the chest was negative. The appearance was that of an infection at the right base. Lipiodol injection showed a moderate saccular bronchiectasis of the

terminal bronchi of the right lower lobe posteriorly, with failure of alveolar filling and some evidence of atelectasis (Fig 7)

At operation on May 3, no adhesions were encountered in the right thorax. After sectioning the inferior pulmonary ligament the lower lobe was amputated between tourniquets, and the stump was closed in the usual manner. A urethral catheter was inserted posteriorly and a Pezzer catheter anteriorly as in Case 4, and at the termination of the operation bronchoscopic aspiration of the tracheobronchial tree was carried out. The pathological diagnosis was bronchiectasis, with chronic suppurative pneumonitis and organized pneumonia.

The patient had a completely uneventful recovery. The temperature rose as high as 101°F on the 2nd postoperative day, but rapidly declined to normal. He was allowed to get up on the 11th day and was discharged on the 18th day after operation.

The patient has remained free of cough and sputum, has gained weight, and is back at his work as a car salesman.

CONCLUSIONS

I believe that one-stage lobectomy is the procedure of choice in the treatment of bronchiectasis, and that with present-day methods it is reasonably safe. Multiple-stage operations should be applied to cases in which the patient is in poor general condition, or in which technical difficulties are expected in the presence of unusually extensive adhesions, so that the possibility of hemorrhage and manipulation may result in a prolonged and dangerous operative procedure.

SUMMARY

Five cases of unilobar bronchiectasis are presented in which one-stage lobectomy was successfully performed. This represents the total experience at the Hitchcock Clinic with the one-stage operation for simple bronchiectasis of a single lobe. Preoperative measures, operative technic, complications and results are discussed.

It is pointed out that in 1 case there were very few adhesions between the normal lobe and the chest, and in 2 cases there were no adhesions. None of these 3 patients developed empyema, and in all, re-expansion of the lung was prompt.

The average postoperative hospitalization was twenty-seven days, the longest period being thirty-nine and the shortest eighteen.

DISCUSSION

DR. THOMAS H. LANMAN, Boston: I agree with Dr. Tyson. He believes, as we do at the Children's Hospital, that it is very much safer to drain all these cases. All our 14 patients have had the one stage operation that he advocates, and we have had the good fortune not to lose any. It is interesting that the histories of most of his patients suggest that the onset of the bronchiectasis dates back to childhood.

DR. HARLAN F. NEWTON, Boston: I agree with Dr. Lanman. In our series of lobectomies for chronic bronchiectasis at the Peter Bent Brigham Hospital, all these patients have been operated on by a one stage procedure, which Dr. Tyson also used. Certainly it is now well established that in experienced hands it is possible to remove a lobe of a lung with a low operative mortality.

There are two points I should like to add which I know Dr. Tyson did not have time to elaborate on. In the first place, the great majority of my cases of chronic bronchiectasis involving the lower lobe of the lung treated by lobectomy have shown involvement of the lingula of the upper lobe, particularly if the interlobar fissure between the lobes is obliterated. Because of this it is my routine practice to remove the lingula of the upper lobe in a so-called lobectomy for lower lobe bronchiectasis, hence the operation should perhaps be called partial pneumonectomy rather than lobectomy.

The second point of interest is that, with the cause of bronchiectasis often obscure, removal of a definitely diseased lobe of the lung does not in every case ensure against recurrent bronchiectasis in the opposite lung. I have just seen such a patient, on whom I performed left lower lobe lobectomy at the age of seventeen, four years ago, and who at that time showed, by bronchoscopy, Lipiodol studies and other examinations, disease limited to the left lower lobe. She has also had no demonstrable sinusitis or chronic upper respiratory infection. She now has definite tubular bronchiectasis of the right lower lobe.

I believe, therefore, that the problem is at present not so much the technical one of safely removing a portion of the lung for chronic infection,—for that has been demonstrated,—as it is a pathological one as to the origin of the primary disease and the prevention of its recurrence.

DR. TYSON (closing): Regarding lingula involvement we looked for this very carefully in our cases and were unable to demonstrate any disease in this area. Bronchiectasis that has been overlooked in the lingula and not treated will almost surely give rise to residual symptoms. If involvement of the lingula is present, this portion of the lung should be removed.

I wish to emphasize again that we found the use of two drainage catheters of the greatest help in the last two cases. I first saw Dr. Churchill use this method of facilitating re-expansion and drainage. Postoperative bronchoscopic aspiration, performed as soon as the intratracheal tube has been removed, is also of great assistance in promoting the comfort and oxygenization of the patient in the first twenty-four hours. This practice was suggested to me by Dr. Lindskog, of New Haven.

I do not believe that the reappearance of bronchiectasis after the removal of a diseased lobe is adequately provided, at least in any significant number of cases. I am inclined to think that if it is discovered subsequent to operation, the Lipiodol injection made before lobectomy may have been at fault.

REPORT ON MEDICAL PROGRESS

RECENT ADVANCES IN THE BIOCHEMISTRY AND THERAPEUSIS
OF POTASSIUM SALTS*

JOHN H. TALBOTT, M.D.,† AND ROBERT S. SCHWAB, M.D.‡

BOSTON

POTASSIUM salts have been employed in the treatment of disease for many centuries. It seems reasonable to believe that in most cases the indications for their use were based on practical experience and were not derived by rational deductions from experimental observations. Recent investigations have enlarged our knowledge of the action of potassium salts, and at present, indications for their use are more precise and less empirical. In this review no attempt will be made to discuss all the recent data concerning the role of potassium in the animal and human organism. Only certain evidence believed to be related to the argument will be presented.

THEORETICAL AND BIOCHEMICAL CONSIDERATIONS

The inorganic salts of potassium are highly ionized in the body. Little attention need be given, therefore, to the anion, the principal effects of the presence of potassium will be assumed to be produced by the cation. There is no recognized hormone in the body that regulates potassium exchange or desoxycorticosterone regulates sodium exchange or parathormone regulates calcium exchange. It is likely that at some future time a hormone or regulator for potassium will be discovered, the lack of recognition of which offers a formidable check on pertinent investigations.

There are three known isotopes of potassium, having atomic weights of 39, 40 and 41. More than 93 per cent of the potassium in animal tissue has an atomic weight of 39¹; nearly all the remainder consisting of that with an atomic weight of 41. The isotope with the atomic weight of 40 is responsible for all or nearly all the radioactivity of potassium. It is extremely rare, and does not appear to be more concentrated in animal tissue than elsewhere in nature. No effects of naturally occurring potassium can be attributed with certainty to its radioactivity, nor have any biologic

effects been observed experimentally from irradiated potassium salts that were unlike natural potassium.²

Of the several satisfactory methods for the determination of serum potassium, we believe that the one revised in our laboratory³ possesses certain advantages. The range for serum potassium in healthy men is between 3.5 and 4.5 milliequiv per liter (14 to 18 mg per 100 cc.) in 90 per cent of the subjects, the extreme range is from 3.4 to 4.9 milliequiv per liter.

In this presentation the role of potassium will be discussed under three divisions: as the principal base in tissues and blood cells it is concerned with the regulation of acid base balance of the body, as an insulin antagonistic and epinephrine like substance, it participates in the intermediary metabolism of carbohydrates, as an antagonist of cholinesterase and as the principal base in muscle cells, it is concerned with the transmission of the nerve impulse to the muscle fiber and with the contractility of muscle. While we do not wish to engage in polemics concerning the chemical versus the electrical theory of conduction of the nerve impulse it appears to us that the chemical theory best explains most experimental observations.

The recognition of the participation of potassium in neuromuscular physiology is recent. To be sure, Ringer,⁴ Howell⁵ and others showed that large amounts of potassium in perfusion fluid exert an effect on cardiac action, but only in the last decade have investigations produced data of interest to clinicians. Brown and Feldberg⁶ showed that small concentrations of potassium chloride in perfusion fluid increase the response of sympathetic ganglia to single submaximal preganglionic volleys. They observed also that potassium stimulates the cells of normal and denervated ganglia to discharge. Conversely, Vogt⁷ showed that in the dog, prolonged faradic stimulation of the preganglionic fibers of the superior cervical ganglia produced a decrease in potassium content of the ganglionic tissue. At the motor end-plates potassium has an action antagonistic to that of curare,⁸ and in this action it is similar to prostigmine,⁹ guanidine, ephedrine and Congo red. This suggests that

‡Associate in Medicine, Harvard Medical School; assistant visiting physician, Massachusetts General Hospital.

§Assistant in Neurology, Harvard Medical School; assistant in Neurology, Massachusetts General Hospital.

potassium has an inhibiting effect on the action of cholin esterase. Lastly, Fenn¹⁰ has shown that during muscular contraction potassium leaves the muscle and that not until recovery does it return. These and other significant investigations constitute advances in the clinician's understanding of disease.

In an attempt to simplify this presentation, it has been assumed that the several actions of potassium are independent, although it is likely that subsequent observations will not bear this out. For example, in Addison's disease the action of potassium may not be confined to any one of the three pharmacologic effects, and in the treatment of hay fever the epinephrine-like action may be associated with a change in acid-base balance or in neuromuscular function. It is quite possible that we are misinterpreting some of the actions of potassium, but for the sake of clarity they will be discussed separately and in the order given above.

THERAPEUTIC CONSIDERATIONS

Potassium salts may be prescribed in various forms for oral administration. It is our experience that an aqueous solution of potassium chloride produces less gastrointestinal distress than does the administration of the salt in gelatin capsules or in tablet form. Usually a 25 per cent solution of potassium chloride is prescribed, one teaspoonful of which contains approximately 1 gm of the salt. The quantity to be ingested is therefore easy to calculate. One teaspoonful may be added to a wine-glassful of water, milk, fruit or tomato juice and ingested with little or no gastric distress. Occasionally patients complain that they have been unable to tolerate initial daily doses totaling 6 or 8 gm of potassium chloride. Under such circumstances smaller doses are given at first and the amount is increased daily up to the maximum desired. Those who have been instructed in this manner have been able to take the quantity prescribed without untoward effects. A more detailed description of potassium administration in patients with myasthenia gravis is given below.

Edema

An accumulation of sodium chloride and water in the interstitial spaces is the invariable state in edema, whether this arises from renal, cardiac or hepatic failure. If a hypertonic solution of potassium chloride is given, a two-fold action results. Potassium competes with sodium for body water, and if an adequate amount is not available for both, a portion of the retained sodium is displaced and subsequently excreted in the urine. Secondly, potassium competes with sodium for reabsorption

by the cells of the renal tubules, so that if a large excess of potassium is present in the glomerular filtrate, it depresses the sodium reabsorption and an additional loss into the bladder urine ensues.

In the treatment of edema, Barker¹¹ found that 5 gm of potassium chloride was an effective diuretic. Keith and Binger¹² confirmed this observation in patients and observed, in addition, a diuretic action in normal persons. Mackay and Butler,¹³ however, were unable to detect any significant increase in excretion of sodium or edema fluid following the ingestion of equal amounts of potassium chloride. There is no satisfactory explanation for this failure of agreement among the various experimental observations.

Addison's Disease

The data on patients with Addison's disease appear to be more definitive. This malady is caused in part by a failure in elaboration of one or more hormones of the adrenal cortex, and involves dissipation of sodium and water and retention of potassium and urea. Some authorities hold that the increased concentration of potassium is as important in the pathogenesis of certain symptoms as is the decrease in concentration of sodium. It follows that a high potassium intake may aggravate symptoms of adrenal insufficiency, conversely, a low potassium intake may be beneficial in the treatment of this condition. A practical test, based on this observation, has been devised by Wilder and associates¹⁴ for suspected adrenal insufficiency. Five gm of potassium citrate is given daily for approximately three days. The patient, meanwhile, is given a diet low in sodium content. A decrease in concentration of serum sodium, an increase in output of sodium in the urine and symptoms of adrenal insufficiency follow if the presumptive diagnosis is correct. In the treatment of Addison's disease a low potassium intake (less than 2 gm per day) has been recommended, although we have been unable to confirm its reported merits in the series of cases in which we are interested.

Recently, an entirely new concept of the value of potassium in Addison's disease has been proposed. If desoxycorticosterone acetate, a synthetic sterol similar to the sterols isolated from the adrenal cortex and useful in the treatment of Addison's disease, is given in excessive amounts it produces an increase in concentration of serum sodium, a decrease in concentration of serum potassium¹⁵ and an exacerbation of malaise, weakness and gastrointestinal symptoms. The effects from over-treatment of patients with Addison's disease are analogous to those of patients with diabetes mellitus who have received an unnecessarily large amount of insulin. Following the assimilation of excessive

quantities of desoxycorticosterone acetate, the level of serum potassium in Addison's disease may decrease to as low as 2.5 milliequiv per liter. Generalized paralysis of the skeletal musculature may occur, as in periodic paralysis (see below), at this level of serum potassium. For the sake of clarity, it may be reiterated that a high potassium intake is harmful in adrenal insufficiency, but beneficial in patients who have been given inadvertently an excess of the active material during treatment.

Obesity

The use of potassium salts in the treatment of obesity has been recommended by Rusk.¹⁴ It was his experience that a high protein intake supplemented by 4 gm or more of potassium chloride daily constituted an effective anti-obesity regimen. Undoubtedly the initial loss of weight was associated with the diuretic action of potassium salts. After this effect has passed restriction of caloric intake seems most essential.

Diabetes Mellitus

There are several reports that potassium is associated with assimilation and utilization of carbohydrates in the body. McQuarrie and his associates¹⁷ observed in 4 diabetic children a decreased tolerance to glucose following the ingestion of 12 to 35 gm of potassium chloride. Gellhorn and Skupa¹⁸ demonstrated that the rate of absorption of glucose from the intestines of frogs is increased by the presence of potassium chloride. Silvette and Britton noted a loss of glycogen from the liver¹⁹ and from the skeletal and heart muscle²⁰ and an increase of blood sugar following the intraperitoneal injection of potassium acetate. Furthermore, it has been known for more than a decade that a decrease of serum potassium is associated with symptoms of insulin shock. Lastly, in a susceptible person, either an injection of insulin or a high-carbohydrate meal may induce an attack of periodic paralysis with decrease of serum potassium. It may be concluded from these data that potassium has a biological action antagonistic to that of insulin. Clinically, little advantage has been taken of this effect, although McQuarrie et al. have shown that insulin hypoglycemia in diabetes mellitus may be controlled partially with potassium chloride. Further trial of potassium salts in persons difficult to regulate with insulin seems indicated.

Allergic Diseases

Another action of potassium which in many respects is opposite to that mentioned above is its epinephrine-like effect. This has been utilized in the treatment of allergic diseases. Bloom²¹ reported beneficial effects in 29 patients with hay fever using

1 or 2 gm of potassium chloride daily. Many were improved within twenty-four hours, and a few more were improved or completely relieved of symptoms within three days. Bloom recommends daily ingestion of potassium during the entire hay fever season. Cessation of ingestion may be followed by exacerbations of symptoms. Rackemann²² has been unable to confirm these findings using similar quantities. He has not abandoned the use of potassium salts, however, and believes that further clinical trial is indicated before making a final commitment. Patients with bronchial asthma do not benefit from potassium chloride so consistently as do those with uncomplicated hay fever.²³

A discussion of urticaria concludes the allergic manifestations. Rusk and Kenamore²⁴ treated 6 patients suffering from this disease with an acid ash diet, high in protein (which is also high in potassium) and low in sodium. In addition, from 4 to 6 gm of potassium chloride was prescribed daily. All the patients responded to this treatment. Subsequently, a group of 20 patients were treated with similar results. These observations could not be confirmed in 8 patients by Cohen.²⁵

Acid-base studies in allergic diseases are few in number, and those which are reported are not complete. Rusk and his associates²⁶ observed a slight increase above normal in concentrations of serum potassium during exacerbations of bronchial asthma. Clinical improvement was accompanied by a decrease in concentration. At no time was the average range for serum potassium in allergic patients as low as the average range for normals. These authors' interpretation of the higher potassium levels is similar to that advanced by us for Ménière's disease, namely, an elevation in the serum is indicative of a migration of this electrolyte from extravascular areas.

The hypothesis advanced by Bloom²¹ in explanation of the beneficial effect of potassium in allergic manifestations was that it participated as an electrolyte in the acid base balance of the blood. He assumed that the major disturbance was an altered electrolyte metabolism with involvement of the adrenal glands. This explanation is somewhat difficult to accept. One more acceptable to us is an action on the sympathetic synapses or neuromuscular junctions and restoration of vasomotor tone. This is consistent with the data and conclusions of Camp and Higgins.²⁶ A constriction of the bronchioles induced by histamine could be relieved as promptly and completely by potassium as by epinephrine. They conclude that one function of epinephrine is the maintenance of an optimum potassium level in the body and that changes in potassium are responsible for typical changes ascribed previously to epinephrine.

The objections raised by Engelsher²⁷ to the treatment of allergic diseases with potassium may be refuted in part. In a series of 64 patients with various allergic manifestations he noted epigastric pain and other intestinal disturbances in a majority. Such symptoms are more likely to develop within a day or two after beginning the regimen. Although he gave no data on the duration of treatment, it is reasonable to believe that his patients took potassium an insufficient length of time to warrant satisfactory conclusions.

Familial Periodic Paralysis

Familial periodic paralysis was one of the first neuromuscular disorders to be treated systematically with a high potassium intake.²⁸ This malady is characterized by spontaneous attacks of flaccid paralysis of the muscles of the extremities, with a concomitant decrease in serum potassium.²⁹ The concentration may be as low as 2.5 milliequiv per liter, a level that may also be reached during paralysis from overtreatment of Addison's disease with desoxycorticosterone acetate. Paralytic seizures have been induced in susceptible persons by injections of epinephrine and of insulin and by ingestion of a high-carbohydrate meal. Each of these procedures causes a diminution in concentration of serum potassium in normal as well as in afflicted persons. The daily ingestion of 2 to 5 gm of potassium chloride or potassium citrate appears to be effective in preventing paralytic episodes. A boy whom we have been following for more than two years has experienced a marked diminution in the number of attacks per year on such a regimen and is able to live a relatively normal life. The only time he suffers from paralytic attacks at present is after overindulgence in carbohydrates.

The pathogenesis of paralysis of the familial periodic type has not been defined. No change in cholin esterase activity of the serum has been demonstrated. The absolute level of serum potassium appears to be less of a factor in inducing an attack than is a diminution per se in concentration of this constituent. Controlled metabolic experiments have failed to demonstrate a loss of potassium from the body following water diuresis.³⁰ A migration of potassium from the serum into certain tissues prior to or during the paralytic stage undoubtedly occurs. It is suggested as a hypothesis that the migration is accompanied by a lowering of concentration of potassium in certain synapses of the central nervous system or at the neuromuscular junctions of affected muscles. The prevention and treatment of attacks by potassium ingestion lend weight to this hypothesis.

Myasthenia Gravis

Myasthenia gravis is another neuromuscular disorder which responds in a remarkable manner to the ingestion of potassium.³¹ The mechanism of weakness in this disorder is unknown, but it has been suggested that it is associated with an increase of cholin esterase activity at the neuromuscular junction and a diminution of available acetylcholine. Relief from symptoms of weakness is accompanied by restoration of the disordered equilibrium of the chemical mediators at this point.

Potassium chloride was first used in the Massachusetts General Hospital in the treatment of patients with myasthenia gravis in 1936. From 10 to 10 gm per day was prescribed in addition to prostigmine. Three patients, all severely afflicted, believed that they were improved on this regimen. If 5 gm of potassium chloride was taken simultaneously with 15 mg of prostigmine, the efficiency of prostigmine was increased and the effect was prolonged. No diminution in the amount of prostigmine required to control the patients' symptoms, however, was observed. In 1937 potassium chloride was recommended to 3 other patients with myasthenia gravis. Benefit was admitted by only one. The following year the use of potassium chloride was reinvestigated. At that time large amounts were given with striking benefit. The ingestion of 10 to 12 gm, three times a day, in 5 cases was followed by a significant reduction in the amount of prostigmine needed. In patients whose daily requirements were from twenty to thirty prostigmine tablets (15 mg each) by mouth, it was possible when in the hospital to reduce the number to two or three if large amounts of potassium salts were taken.* A reduction in the cost of treatment and an opportunity to maintain a more complete state of remission were achieved. Up to the present 24 patients have taken or are taking with benefit large amounts of potassium chloride and smaller amounts of prostigmine than formerly.³² In addition, 7 patients began the ingestion of potassium chloride but discontinued it subsequently, either because they were not helped or because of untoward symptoms. It appears to be impossible to regulate patients on potassium chloride alone. The failure of Minski³³ in the treatment of myasthenia patients with potassium chloride and prostigmine may be attributed to inadequate amounts used.

A satisfactory method for the ingestion of large amounts of potassium chloride embraces the use

*On the outside when one is dealing with patients who are of course much more active than a person in a hospital bed all day no such reduction in prostigmine occurred. In these cases the amount of prostigmine was reduced from twenty to fifteen tablets and in others from ten to six or approximately 20 to 40 per cent.

milk as a vehicle. We have recommended that patients prepare each day a mixture of the following

| | |
|--------------------|-------------------------|
| Milk | 1 quart |
| Cream | ½ cup |
| Egg | 1 |
| Sugar | 2 teaspoonfuls |
| Potassium chloride | 8 teaspoonfuls (30 gm.) |

The formula may be taken in three divided doses with regular meals. Other patients prefer a 25 per cent aqueous solution of potassium chloride flavored with a small amount of peppermint water. Thirty cubic centimeters of such a mixture may be taken three times a day with meals. Potassium chloride may be prescribed in 1-pound amounts of the dry crystals for the patient to prepare his own solution, or as the 25 per cent solution in large quantities.

Recently it has been observed that a combination of guanidine hydrochloride (0.0125 gm.), potassium chloride (5-10 gm.) and prostigmine (15 mg) taken with meals gives a sustained effect for three or four hours. Only in most desperate cases is such a combination of anti myasthenia drugs necessary. It is to be noted that potassium chloride as well as prostigmine and guanidine are potent anti-curare substances.

Ménière's Disease

The history of the use of potassium chloride in the treatment of Ménière's disease or Ménière's symptom-complex seems worth relating. Several years ago Mygind and Dederind³¹ assumed that this malady was associated with a disturbance of water and salt metabolism. A waterlogged labyrinth was thought to be at fault and a dehydrating regimen was therefore indicated in treatment. Furstenberg and his associates³² reinvestigated the problem sometime later, and showed evidence that a retention of sodium was of greater pathogenic significance in the production of symptoms than was a retention of water. They recommended a diet with a low sodium content and the ingestion of ammonium chloride. Since both regimens achieved certain success, it seemed expedient to us³³ to investigate the constituents of the blood before and after treatment. This was done in a group of 33 patients.³⁷ No increase in concentration of serum sodium was observed during a relapse. This appeared to exclude sodium retention as a significant pathogenic factor in production of symptoms. In 4 patients who were having severe symptoms, however, an increase in concentration of serum potassium was observed. This prompted us to consider several aspects of the regimens which have been recommended and found successful in many patients.

In a diet devised to provide for a low sodium

content, some increase in potassium usually occurs. Since a low-sodium and high-potassium diet was effective, it seemed reasonable to try a normal diet with potassium chloride added. To achieve this, approximately 6 gm. of potassium chloride in an aqueous solution was given daily. No modification of the normal diet was recommended. To date more than 50 patients have been treated in this manner. Most of those who have followed the recommendations have been benefited, although few have been relieved of all symptoms.

Those most severely affected appear to be helped most. Several patients who were having many severe attacks per month have had the incidence reduced to only a few a year. The severity and duration of each attack have been likewise diminished. All except one or two have been able to lead a relatively normal life without the fear of an unexpected incapacitating attack. Several discontinued the daily ingestion of potassium and experienced a return of symptoms after a period of a few days, return to the regimen was followed by a satisfactory alleviation of symptoms. One intelligent but skeptical patient performed this experiment three times before he was convinced of the merits of the high potassium intake. Similar satisfactory results have been reported by Chapman,³⁸ Graves,³⁹ Reese⁴⁰ and Schneider.⁴¹ Improvement in hearing has been claimed by some patients. We are skeptical concerning this alleviation. With diminution in tinnitus some improvement in hearing would be expected. The precise action of potassium chloride in patients with this syndrome is not known. As a working hypothesis it has been assumed that an increased concentration of serum potassium is indicative of the disruption of normal chemical mediation of impulses in the eighth nerve. Ingestion of potassium may restore normal equilibrium.

Because of the benefit in Ménière's syndrome, potassium salts have been given to patients who complained of one or more symptoms of the classical syndrome, but in whom the clinical picture did not warrant a presumptive diagnosis of this malady. The symptoms complained of included vertigo, tinnitus and deafness. Since potassium chloride is a relatively harmless material, its use seems justified when other forms of therapy are ineffective. The same amounts are recommended as in the treatment of Ménière's syndrome.

Cardiac Disease

Changes in cardiac action with variation in concentration of serum potassium have been reported. Inversion of T₁ and T₂ has been noted⁴² in dogs with high serum potassium levels. In 1930 Wiggers⁴³ reported alleviation of ventricular fibrillation in dogs following perfusion with a solution of po-

potassium chloride Sampson and Anderson⁴⁴ utilized this observation in human beings in the treatment of auricular and ventricular ectopic beats with tachycardia. In doses of 1 to 16 gm, potassium chloride was effective in restoring normal rhythm in 50 per cent of a small group of patients. It has been suggested that alteration of the electrocardiogram in acute coronary thrombosis⁴⁵ may be due in part to alteration in the level of potassium in the muscle.

Untoward Effects

The ill effects of excessive potassium ingestion are believed to be few. Oral administration of as much as 40 gm per day to patients with myasthenia gravis produced no recognized untoward effects. Gastrointestinal distress usually develops before a toxic amount has been ingested. With onset of gastrointestinal distress assimilation is retarded and excessive quantities are not absorbed. The harmful effects of potassium in untreated Addison's disease have been discussed. Other conditions associated with a diminished concentration of serum sodium and increased concentration of serum potassium, such as heat cramps, acute nephritis, pemphigus and dehydration, might be aggravated. Scudder, Zwemer and Truszkowski⁴⁶ called attention to the possible toxic effects of a high serum potassium in acute intestinal obstruction. With the storage of blood and development of blood banks the concentration of the potassium in the transfusion fluid must be considered. If whole blood is stored⁴⁷ there is a slow migration of potassium from the blood cells into the plasma. When this concentration exceeds 10 milliequiv per liter the blood is probably unsuitable for intravenous use in human beings.

SUMMARY

Certain aspects of the role of potassium in the body are reviewed. The action of potassium appears to depend on its effect as an electrolyte, as a substance concerned with carbohydrate metabolism, as an important mediator of the nerve impulse and as a participant in muscle contraction.

In allergic manifestations, Ménière's syndrome and familial periodic paralysis, from 2 to 10 gm of potassium chloride per day is effective. In myasthenia gravis from 30 to 40 gm per day may be indicated. In a few conditions a low potassium intake is desirable.

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTHEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., Editor

CASE 26141

PRESENTATION OF CASE

First Admission A thirty four year-old house wife was admitted to the hospital complaining of vomiting of four days duration

The patient had always been well until sixteen years before admission when, at the age of eighteen she became ill with the following symptoms: ankle edema, dyspnea, palpitation and cough. She had difficulty remembering her sickness. Supposedly the illness lasted about two weeks, and she was then apparently well until eight years before entry when another identical attack occurred. She was then told that she had heart trouble. Some five to six years before entry she had had an attack of tonsillitis, with "occasional" sore throats thereafter. About four years before entry another two-week illness was diagnosed as being due to a "leaking valve." Since that time she had been placed on digitalis, which she did not take regularly. Nine months before admission the patient was injured in an automobile accident, suffering severe bruises, without fractures, to the right chest. She was placed in an outside hospital where the right chest was tapped a few weeks later and a "large amount" of fluid removed, the character of which was not reported. This resulted in some improvement, but she continued to note orthopnea, cough and palpitation, without known ankle edema. After three months hospitalization she went home and remained in bed, and continued with digitalis. Two weeks before entry she was taken to a summer camp and was moderately active there, but was brought home five days before admission because of dyspnea, palpitation, ankle edema and cough. A physician ordered her to bed and placed her on digitalis, one "pill" every two hours. Instead she took two pills every two hours and began to vomit after having taken ten pills. She vomited every meal thereafter, but continued, nevertheless, to take the digitalis. It appeared that she took a total of 44 gr. in the five days before her admission, it was not known how much was regurgitated. She became quite orthopneic, edema of the legs increased rapidly, and she was alleged to have observed yellow vision but no diarrhea. For about two weeks before

admission she occasionally coughed up "bloody sputum, and she had lost 30 pounds in weight during the ten months before entry

Physical examination revealed an orthopneic, drowsy, pale, slightly cyanotic, ill appearing woman, who had a malar flush and distended neck veins and who raised small amounts of bright red sputum. The heart was enlarged to the left to the region of the anterior axillary line and to the right where its border faded into an area of lung dullness. There was a questionable diastolic apical thrill. The rhythm was grossly irregular, the apex rate was 69, the radial 54. There was a loud heaving impulse. A diastolic murmur was heard at the apex, and a soft blowing diastolic murmur over the aortic area. The pulmonary second sound was accentuated. The blood pressure was 130 systolic, 90 diastolic. The chest was dull up to the angles of the scapulas posteriorly, high in the axillae laterally, and to the fourth ribs anteriorly. The right base was flat. Moist rales were heard in the area of dullness. No rales or breath sounds were heard at the right base. The abdomen was moderately distended with questionable ascites. The liver edge was palpated three fingerbreadths below the costal margin. There was edema of the sacrum, and deep pitting edema of the lower legs. The remainder of the physical examination was negative.

The temperature was 102°F., the pulse 90, and the respirations 30.

Examination of the blood revealed a red-cell count of 4,800,000 with 90 per cent hemoglobin and a white-cell count of 16,700 with 85 per cent polymorphonuclears. The urine showed a large trace of albumin, and the sediment contained 10 white blood cells, 5 red blood cells and occasional granular and hyaline casts per high power field. A stool was guaiac negative. A blood Hinton test was negative. The blood non-protein nitrogen was 44 mg. per 100 cc., the serum protein 6.3 gm., and the icteric index 8 per cent, a direct van den Bergh test was slightly above normal.

Roentgenograms of the chest showed that the diaphragms were unusually high on both sides. The lower portion of the cardiac shadow was obscured by the high diaphragm and by hazy dullness occupying both bases. The heart shadow, however, appeared to be grossly increased in size, both to the right and to the left of the spine. The upper portions of the lung fields were clear. An electrocardiogram taken two days after admission showed auricular fibrillation, with an auricular rate of about 400 and a ventricular rate of about 80. The T wave changes were consistent with a digitalis effect.

In about three weeks the patient's temperature gradually fell from a daily average of 100 to 101°F to normal. The apical pulse averaged some 80 to 90 beats a minute, with a radial deficit of 3 to 7 beats. The white-cell count remained elevated around 14,000. A seven-foot film of the heart taken three weeks after admission demonstrated that the greatest enlargement was across the base in the region of the auricles. The pulmonary conus was prominent, and there was an increase in the angle of the bifurcation of the trachea. There were several hazy areas of mottling distributed throughout both lung fields. The right base was clear. Both hilus shadows were grossly increased in width and density, a finding apparently due to venous congestion.

The patient continued to raise decreasing amounts of blood-tinged sputum throughout the hospital stay of seven weeks. She was digitalized, given bed rest and was discharged slightly improved.

Second Admission (almost four years later) The patient had been taking 1½ gr of digitalis daily and had been fairly well, with only limited activity, until ten weeks before entry, when she developed a head cold. She did not go to bed, and when the cold cleared, she noticed a recurrence of ankle edema, dyspnea, orthopnea and cough. There were no hemoptyses or other symptoms.

Physical examination was essentially unchanged from that of four years previously, except that a late diastolic rumble and early systolic blowing murmur were heard at the apex. An early blowing diastolic murmur at the base was best heard at the second intercostal space on the left. Another examiner found an early diastolic murmur following immediately after the second pulmonic sound (Graham Steele murmur). The red-cell count was 6,500,000 with 112 per cent hemoglobin, and the white-cell count 14,500 with 80 per cent polymorphonuclears. The urine showed a +++ albumin test. Roentgenograms of the chest showed that the heart had a mitral configuration and that there was haziness in the right lower lung field suggestive of multiple small infarcts. Eight days later a portable chest plate showed a small amount of fluid in the right pleural cavity. A definite infarct was not visible. The electrocardiogram was unchanged from the previous admission. The venous pressure was 120 mm of water.

With bed rest, digitalis and diuretics the patient gradually improved and was discharged on the nineteenth hospital day to a nursing home.

Final Admission (six months later) The patient was not well following her discharge. She had repeated hemoptyses and led a life of invalidism. She was bed-ridden for six weeks before her final admission. Nausea and vomiting were re-

lieved five days before entry by omitting digitalis, but her edema increased. It was stated that she had always had an abnormal tendency to bruise easily, but it had become more marked. Mottling appeared over her arms and legs, and large confluent black-and-blue ecchymoses on her fingertips and toes, these were sensitive at first. There had been no pain in the left upper quadrant of the abdomen. She had, however, passed "red" urine during the week before entry, so much so that she wondered if her menses had not begun.

Physical examination revealed an apathetic woman who appeared gravely ill. The malar flush was prominent and was purplish. There were many splinter hemorrhages and large ecchymotic areas on the tips of the fingers and toes, together with mottling of the extremities. The entire body, including the face, eyelids and arms, was waterlogged. The breath was foul but not uremic. The neck veins were distended, and yet the patient was able to lie flat in apparent comfort. The chest was almost clear of rales, but there were signs of fluid on the right. The heart was as previously described except that there was a grossly irregular but fairly consistent bigeminal and occasionally trigeminal rhythm, with a pulse deficit of 40 and a soft mid-diastolic murmur maximal at the pulmonic area and transmitted down the left border of the sternum. The pulmonic second sound was much louder than the aortic. The blood pressure was 140 systolic, 80 diastolic. The liver was just palpable, and the abdominal wall was so edematous that further examination was impossible.

The temperature was 100.2°F, the pulse at the wrist 86, and the respirations 20.

The blood showed a red-cell count of 6,600,000 with 125 per cent hemoglobin, and a white-cell count of 20,800 with 84 per cent polymorphonuclears. The color index was 1.05, and the mean corpuscular volume 100. The urine showed a ++++ albumin test, and the sediment contained 5 to 6 red cells and innumerable white cells per high-power field. The serum non-protein nitrogen was 78 mg per 100 cc. The hematocrit was 65, the uncorrected sedimentation rate 0.2 mm per minute, the blood clotting time 10 minutes, the bleeding time 1.5 minutes, and the clot retraction normal. The venous pressure was 170 mm of water. An electrocardiogram showed low T₁ and T₂ and inverted T₃, Q₃ was 7 mm, there were runs of bigeminal rhythm and auricular fibrillation, with ventricular premature beats.

On admission the patient appeared to be *in terminus*, but following treatment with Salyrgan and omission of digitalis she rallied for a time. The temperature ranged upward to 100 or 101°F daily, and although she had sufficient diuresis, she failed

gradually and went into a state of peripheral vascular collapse with icy extremities, impalpable pulse, absent blood pressure, extreme cyanosis, dyspnea and profuse sweating. She was placed in an oxygen tent, but died on the twentieth hospital day.

DIFFERENTIAL DIAGNOSIS

Dr. T. DUCKETT JONES. It is very interesting that ankle edema, dyspnea, palpitation and cough are frequently repeated throughout the record, and it is fair to assume that at the age of eighteen the patient had congestive heart failure. I also should be willing to suggest in view of the absence of a previous history of heart disease that she had rheumatic heart disease and had insidiously developed mitral stenosis. It is further suggested that active rheumatic fever was probably responsible for the congestive failure.

At the age of twenty-six she again had what seems to be a mild episode of congestive failure, probably again on the basis of acute rheumatic fever. At thirty she had another episode and valvular heart disease was diagnosed. Auricular fibrillation may have begun at this time, but I should doubt it because of the subsequent events.

Following the automobile accident, she had a long period of illness with weakness and congestive failure, and I presume that the right chest fluid was either the fluid of congestive failure or of pleuritis coincidental with active rheumatic fever. Whether the accident had anything to do with precipitating the rheumatic fever is problematical but we have seen a good many cases in which there was an apparent association between an operation, accident or non-streptococcal event and recurring rheumatic fever.

Apparently she had digitalis intoxication, although there seems to be some doubt as to the actual amount of the drug which the patient retained.

It is obvious that for almost a year prior to admission to the hospital she had had some active disease process which resulted in a great deal of weight loss, and it is possible that the accident increased the symptomatology. We are not certain, however, of the actual existence of symptoms prior to that time. It is possible also that auricular fibrillation may have started shortly after the accident and that its onset began the gradual downhill progress.

The distended neck veins and bright red sputum suggest that she may have had a pulmonary infarct or infarcts.

Apical thrill is not common in rheumatic heart disease with auricular fibrillation for obvious reasons.

The accented pulmonic second sound is probably indicative of mitral stenosis.

The patient had slight fever and perfectly good evidence of an active disease process. Congestive failure was present in a patient with probable mitral and aortic disease, and there was nothing very unusual about the picture as presented at the time of the first admission.

The negative Hinton test is of interest in view of the differential diagnosis to be discussed later. I regret that there was no venous pressure recording on the first admission. It might be of some help in clarifying the subsequent events.

The sedimentation rate was not determined, but this would not have been helpful in view of the presence of a large liver.

The pulmonary conus was prominent, and there was an increase in the angle of the bifurcation of the trachea. She probably had quite large auricles, and conspicuous enlargement near the base of the heart would probably account for this x-ray finding.

There were several hazy areas of mottling distributed throughout both lung fields. This is in keeping with pulmonary infarcts or pulmonary changes seen at times during rheumatic fever.

Seven weeks is a very long period for a patient with ordinary congestive failure to have hemoptysis. She did not have spells of severe orthopnea with pulmonary edema, which are common in the patients with mitral stenosis who have hemoptysis. Apparently she improved slowly, despite the fact that during her few weeks stay in the hospital she had evidence of something continuously going on in the lungs in addition to the picture of congestive heart failure. The symptomatology was very much the same as that of her earlier bouts of congestive failure.

Physical examination at the time of the second admission, nearly four years later, showed a decided change in the patient. The description of a Graham Steele murmur raises a question of considerable interest because such murmurs are rare, and one wonders if we are justified in making such a diagnosis unless congestive heart failure was present. It may be possible that this patient had two diastolic murmurs of very similar quality at the base of the heart.

The red-cell count was 6,500,000 with 112 per cent hemoglobin, and the white-cell count 14,500 with 80 per cent polymorphonuclears. This is the first time we have noted any evidence of polycythemia. The white count may be explained entirely on the basis of the polycythemia.

I do not know the extent of the peripheral edema, but I notice in the treatment that the patient received diuretics as well as digitalis. The

question might be raised as to why she developed such a high red-cell count. This polycythemic tendency was not very pronounced at the time of this admission. Apparently the tendency increased considerably in the six months between the second and the third or final admission. I think we can assume that the patient had pulmonary infarcts or something by x-ray which was very suggestive of pulmonary thrombosis. There had been a change in the clinical picture, and the pulmonary system began to assume a more and more important role. The cyanosis was very striking. Extensive cyanosis and ecchymotic areas over the tips of the fingers and toes are suggestive of extensive pulmonary changes and probably alteration of the minute peripheral vessels.

"The neck veins were distended, and yet the patient was able to lie flat in apparent comfort." That is a striking feature. I presume the venous distention was noted with the patient sitting erect. Such a combination is most unusual. There was obviously no extensive left-sided cardiac failure, because such patients are not able to lie flat comfortably. In children with rheumatic disease and cardiac failure one often sees right-sided heart failure, with high venous pressure, edema of the face, a large liver and peripheral edema. The lungs remain remarkably clear and the patient often prefers to lie flat. This is rarely seen in adults. In this patient there was little or no elevation of the venous pressure, and despite the lung changes the patient could lie flat. This strongly suggests that the pulmonary changes were not the result of ordinary congestive heart failure (left-sided failure).

"a soft mid-diastolic murmur maximal at the pulmonic area and transmitted down the left border of the sternum." This again could denote either an aortic diastolic murmur or the Graham Steele murmur of relative pulmonary insufficiency. The pulmonary second sound was louder than the aortic second sound. The patient had mitral stenosis and hence might have a good reason for an accentuated pulmonic second sound, but that is a helpful feature of the differential diagnosis that I shall give a little later.

"The liver was just palpable." This is another finding which suggests little, if any, right-sided heart failure. Large painful livers are often an outstanding feature of failure of the right side of the heart.

Apparently she did not have a palpable spleen at any time. The blood examination still showed a definite polycythemia, with perhaps infection as indicated by the increase in polymorphonuclears. I should doubt any serious alteration in the blood-forming organs.

The hematocrit was 65, in keeping with the polycythemia. There was abundant evidence that the patient did not have thrombocytopenic purpura. There was a distinct increase in retention of the nonprotein nitrogen since the preceding admission. A level of 78 mg per 100 cc. is fairly high for a patient with ordinary congestive failure.

"The venous pressure was 170 mm of water." That is not very high. I suppose it is an indication of some degree of congestive failure, especially of the right side of the heart, but there is considerable variation in venous-pressure technics. I am not familiar with the exact routine used in the medical wards, but with probably the same method, we usually observe tremendous increases in venous pressure even long before evidence of peripheral edema. Here was a liver that was but little enlarged, and a patient who could lie flat in bed. I should presume on the basis of these facts that congestive heart failure was not severe.

Dr. White will probably mention the electrocardiogram because it offers suggestive evidence of the presence of pulmonary infarction. Also the probability of pulmonary hypertension comes into play because of the finding of a very strong pulmonic second sound and the persistent hemoptysis. The story and findings fit in with massive pulmonary infarction or thrombosis.

This is an exceedingly difficult differential diagnosis. It is not the usual problem met in cases of rheumatic fever and heart disease. The first few years are in keeping with those of a patient who has developed insidious rheumatic heart disease and probably repetitive bouts of congestive heart failure. It is safe to assume that she had rheumatic heart disease, mitral stenosis with auricular fibrillation, probably mild aortic disease and, possibly, pulmonary disease. These features, however, do not explain the patient's death. In other words, I do not believe she died as a result of either rheumatic heart disease per se or of acute rheumatic fever in the ordinary sense of fulminating rheumatic fever. There are some features difficult to explain, for instance the massive edema and the relatively little evidence of nephritis. The retention of nonprotein nitrogen and the urinary findings hardly explain the death on the basis of acute glomerulonephritis, so I think we must try to explain the syndrome largely on the basis of a disease or change in the blood vessels.

The first thing that comes to my mind is periarteritis nodosa. She had many of the features of this disease, but not all of them, and the blood picture is distinctly contrary to the usual finding. We know that in such cases 80 per cent may show renal changes. No peripheral nodes were noted. I should say that the chief feature against peri-

arteritis nodosa is the fact that there was not enough evidence of arterial change in various locations. In periarteritis nodosa the large vessels are not usually involved, in this patient, apparently there were changes in the large vessels of the pulmonary tree. In addition, there have been some extraordinary pulmonary specimens reported in which extensive arterial nodules occurred in the lung tissue, without appreciable alteration in the pulmonary circulation.

I think the advanced edema was not entirely the result of congestive heart failure, but to some extent probably dependent on hypoproteinemia. There is no mention of the serum protein during the last illness.

At the end the patient presented a picture much like Ayerza's disease. That, as you know, is supposed to be syphilitic in origin, but we have no evidence in this patient of a syphilitic process. There have been a small number of pathologists who have constantly written about pulmonary changes in rheumatic fever of an arterial nature. Four years ago Parker and Weiss¹ reported a case which, except for two features, was very similar to this one. Their patient had pulmonary edema in increasingly severe episodes and died, but did not have massive peripheral edema. Gouley² and his co-workers in Philadelphia have written repeatedly about pulmonary fibrosis and changes that occur in rheumatic fever and have stated that the reason for failure of the right side of the heart is often the result of pulmonary change. We have seen very little of this in gross pathological specimens and no real syndrome clinically. However, Cash,³ at the University of Virginia, has been impressed with the great frequency with which you get in fatal changes in moderate sized and small sized blood vessels in patients with rheumatic fever, particularly in those who have had the disease over a period of years. The case Parker and Weiss described had extensive changes in the fair sized arteries of the lungs and in the small arterioles. They compared this change with that which is found in malignant nephrosclerosis, and I think it is fairly obvious that this patient must have had some change in the blood vessels of the lung over a fairly long period of time. She probably had hypertension of the pulmonary circulation and coexistent changes in the blood vessels in other parts of the body. Changes in the pulmonary vessels were probably responsible for the rather progressive nature of the disease and for the fatal outcome. Whether it can be said that she was suffering from chronic cor pulmonale I do not know. Ayerza's disease is of course very much of this nature, but I do not believe that the patient had this type of change. However, she

did not present the syndrome of acute cor pulmonale with a rapidly terminal course. The chronicity of the process is somewhat against ordinary pulmonary infarction or thrombosis as the cause of the whole difficulty. I think she would have died much sooner with a less severe generalized disease process if this had been true. The picture, as I see it, is probably one of pulmonary arterial disease, possibly on a rheumatic basis. Of the latter I am not sure, but I should say that the process was not limited to the pulmonary arteries but extended throughout the body, although the changes were more pronounced in the lung and kidneys.

DR. FREDERICK T. LORD: Was a blood culture taken?

DR. TRACY B. MALLORY: I can find no record of it.

DR. LORD: The picture suggests that she might have had right sided endocarditis with pieces breaking off and going into the lungs.

DR. EDWARD F. BLAND: The x-rays are not here, but I should like to raise the question of a possible complicating interauricular septal defect plus the mitral stenosis. It would be difficult to make this diagnosis without seeing the films and the electrocardiogram. This combination may give a curious x-ray picture with especially prominent lung changes. I should like to ask Dr. Jones if he would want to consider that combination here.

DR. JONES: I think it is possible but there is no real evidence to support the diagnosis. This whole thing could be explained on the basis of a congenital defect in addition to mitral stenosis, but there is no early story suggesting a congenital defect, and the age of the patient is somewhat against such an association of lesions over a period of at least sixteen years. I thought very seriously of whether something could have developed in the nature of an arteriovenous aneurysm, but there is no evidence to support such a diagnosis. It is possible that such a shunt may have had something to do with the picture.

DR. PAUL D. WHITE: Dr. Jones has done extremely well. Have we the electrocardiogram? It would be of value in determining whether an interauricular septal defect was present. I find that the angle of the axis is only 90°. The only cases of congenital auricular septal defects that we have followed through have had marked right axis deviation (110° or more). This finding is against the diagnosis of auricular septal defect. The electrocardiogram, to be sure, does show rather large Q waves in Leads 2 and 3, which may be explained on the basis of any factor causing enlargement of the right ventricle. It is possibly the result

of a cor pulmonale of the acute, subacute or chronic type. But the record is not clear-cut, perhaps due to a combination of factors.

Some of the events that had happened in the past were probably episodes of pulmonary infarction. We know that such infarcts can occur in acute rheumatic disease as well as from embolism of whatever cause.

I do not know whether my auscultatory findings were accepted by those who wrote up the record, they are not mentioned here. It intrigued me on the wards a few days before she died that there was a striking diastolic rumble close to the left border of the sternum at its lower end, which was almost as marked as any that I have heard at the apex in mitral stenosis. She had not shown this a year or two before, as we found out by looking back through the outpatient record. It was a murmur that made one think strongly of tricuspid stenosis. It followed a very loud, blowing, early diastolic murmur heard in the pulmonic-valve area. There was no doubt about the pulmonary diastolic murmur being a Graham Steele murmur, it was very loud and heard maximally in the pulmonic-valve area after a very loud second sound. I thought there were three separate murmurs, namely those due to mitral stenosis and to pulmonary regurgitation and something that resembled the murmur of tricuspid stenosis. I do not know whether we suggested the possibility of a right-sided Austin-Flint murmur then, but that came up later.

The final point that interested us was the condition of the fingers and toes (mottling and ecchymoses) and the very marked cyanosis, it made us think of a ball thrombus in one auricle or the other. Because of the novelty of the case we suggested that it might be in the right rather than in the left auricle, but that was a wild guess.

CLINICAL DIAGNOSES

Rheumatic heart disease, with mitral stenosis
Tricuspid stenosis, with auricular fibrillation?
Congestive failure
Pulmonary infarction
Compensatory polycythemia

DR JONES'S DIAGNOSES

Rheumatic heart disease
Mitral stenosis
Auricular fibrillation.
Congestive failure
Compensatory polycythemia
Arterial thrombosis or fibrosis, pulmonary and renal (? rheumatic)

ANATOMICAL DIAGNOSES

Rheumatic heart disease, chronic, with mitral stenosis

Endocarditis, acute rheumatic, aortic, mitral and tricuspid

Cardiac hypertrophy and dilatation

Thrombosis of left pulmonary artery

Thrombosis, massive, of left auricle

Thrombosis, left renal artery, abdominal aorta and common iliac arteries

Pulmonary infarcts, healed

Renal infarcts, fresh and healed

Anasarca

PATHOLOGICAL DISCUSSION

DR MALLORY. This was obviously a most complicated clinical picture, and the autopsy findings were equally complicated and numerous. The primary underlying condition was rheumatic heart disease with mitral stenosis. The degree of mitral stenosis, however, was not severe. The circumference of the valve was 5 cm so that on anatomical grounds under ordinary conditions one would not expect a heart to fail this rapidly. This valve and the aortic and tricuspid valves all showed small pin-point vegetations suggestive of acute rheumatic involvement. We found nothing to suggest bacterial endocarditis. The right side of the heart was very markedly dilated, both auricle and ventricle, and there was considerable bulging of the pulmonary conus, a very characteristic finding in cor pulmonale. The main pulmonary artery was also markedly dilated, and the major branch of the left lung was almost completely occluded by old organized thrombus. The branch to the upper lobe was totally occluded, that to the lower lobe almost completely occluded. There were also several depressed scars on the pleural surface, which on lengthy investigation in the hands of Dr Castleman were eventually proved to be healed infarcts. There was one fresh pulmonary infarct, 7 cm in diameter, in the other lung, not a strikingly large one and not adequate to explain the sudden death.

Another peculiar finding which may possibly have had functional significance was an enormous thrombus in the left auricle which was so large that only a small lumen, a little over 2 cm in diameter, was left. The mouths of the pulmonary veins were impinged on by this thrombus, and it was difficult to understand how the blood got back from one lung.

The other major finding was in the systemic circulation where a large thrombus was found beginning just below the diaphragm in the abdominal aorta and extending all the way down into the iliac arteries. The degree of narrowing varied from one to two thirds of the diameter. It overlaid the mouth of the left renal artery, and the

thrombus extended out into the small intrarenal branches. This and the aortic thrombus were obviously old, being completely organized, the left kidney had shrunk to 25 gm in weight but what remained of the kidney tissue was viable. On the right there was fresh infarction of the major part of the kidney, so I should think there must have been a considerable element of uremia in the picture. Whether it was enough in itself to have caused death, I am not sure. For the dramatic terminal episode I have no explanation. We did not have permission to examine the head. Conceivably something there might have been responsible for it.

Dr. WHITE May I add one further comment about the mid-diastolic murmur in the tricuspid valve area? In the absence of tricuspid stenosis it should be regarded, I think, as right sided Austin Flint murmur.

Dr. JONES What about the blood vessels in the lungs?

Dr. MALLORY I could see nothing in them that I could recognize as a specific arteritis. The larger vessels showed obliteration, which I interpreted as the result of organization of thrombi. The small arteries of the lungs did show diffuse thickening of the walls of the type Parker and Weiss described. This condition was extensive and no doubt contributed to the picture.

Dr. HOWARD B. SPRAGUE Is this a case of partial renal ischemia without hypertension?

Dr. MALLORY We have seen so many that I did not remark about it.

CASE 26142

PRESENTATION OF CASE

A thirty-two-year-old American dye machine operator entered complaining of numbness of the left leg.

Three months before entry he noticed numbness in his left foot. This condition gradually spread up the leg to the thigh and finally to the abdomen. He noticed that the numbness stopped exactly in the mid-line. During the following two months the left chest and arm gradually became involved. The numbness was described as an inability to appreciate pain or to feel things as well as usual. He was unable to distinguish hot from cold but noted that hot water produced a burning sensation which was quite unpleasant and painful. He also

noticed that the right side of his face felt numb while shaving. Two months before entry his voice became weak toward the end of the day and he was unable to produce any sound. He began having attacks of hiccups, usually about 10:00 a.m. These were relieved by drinking cold water. One month before entry he noticed difficulty in swallowing. Solid food seemed to "stick" in his throat. Approximately two months before entry he developed unsteadiness of gait, characterized by deviation to the right, so much so that his friends thought he was intoxicated. During the month before entry he developed right occipital headaches just above the mastoid. These headaches often spread throughout his head. There was no history of tinnitus, dizziness, vomiting, aphasia, or blurring or double vision. These symptoms as they developed lasted until admission with no improvement.

His family and past histories were noncontributory. He had been married eight years. His wife and two children were living and well. There had been no miscarriages.

Physical examination showed a well-developed and well-nourished man in no acute distress. Except for a few slightly enlarged axillary and inguinal nodes the examination was negative. The blood pressure was 135 systolic, 85 diastolic.

A neurological examination gave the following positive findings. There was loss of pain and temperature sensations on the left side of the body. Touch and vibration sensations everywhere were normal. The right pupil was slightly smaller than the left. There was rotary nystagmus. The corneal reflex was absent on the right and active on the left. The hearing was normal. Air conduction was greater than bone conduction. The Weber test was not lateralized. The palate was deviated to the left, and the gag reflex on the right was diminished. There was a questionable weakness of the right side of the tongue. When standing he deviated to the right almost constantly. His tendon reflexes were all active and equal on both sides. The abdominal and plantar reflexes were normal.

The temperature was 98°F, the pulse 76 and the respirations 20.

Examination of the urine was negative. The red blood-cell count was 5,660,000, with a hemoglobin of 100 per cent. The white-blood-cell count was 7400, with 79 per cent polymorphonuclears. A blood Hinton test was negative. On lumbar puncture 15 cc. of clear colorless fluid was withdrawn. The initial pressure was 145 mm of water; the pressure rose to 300 mm on jugular compression and immediately fell to its previous level on release. An alcohol test was positive, and an am

monium sulfate test negative, no cells were found. The total protein was 38 mg per 100 cc, the gold-sol and Wassermann tests were negative.

During the first four days in the hospital he developed nausea, vomiting and increased difficulty in talking and swallowing. He also complained of considerable dizziness, which was partially relieved by lying on his right side. The impairment of pain and temperature sensations gradually spread and involved the left face, as well as the right face and left side of the body. There was considerable nystagmus, although the eyes moved well. His hearing remained normal. During the second and third weeks he was treated with six small doses of x-rays. His symptoms improved somewhat, although none of the important signs which were present on admission entirely disappeared. At the time of discharge from the hospital, during the fourth week, he had slight hypesthesia of the right side of the face but no facial weakness. The nystagmus to the left and the unsteadiness of his right arm and leg had diminished, also the vomiting and hiccups. There was slight but definite improvement in the ability to recognize changes of temperature on the left side. On the other hand, fibrillations and atrophy of the right half of the tongue, signs which were not present on admission, developed during his stay in the hospital.

While at home he continued to improve subjectively. An examination performed by his physician one month after discharge showed marked weakness of the right arm and leg not limited to any muscle group. The uvula deviated slightly to the left. He complained of marked right occipitoparietal headaches. During the following month there was much more marked subjective improvement. The headaches disappeared almost completely, and his walking improved to the extent that he was able to go downstairs without help. His appetite was good, and there was an evident gain in weight. There was only an occasional hiccup. Examination two months after discharge showed slight nystagmus. There was no definite facial weakness, but wrinkling of the forehead was perhaps slightly less on the right than on the left. The uvula was in the midline but deviated to the left with phonation. Sensory impairment similar to that described above persisted. Position sense was normal. The reflexes were active and equal. There was considerable staggering on walking.

During the third month after discharge from the hospital his walking became progressively worse, his headaches returned and he became decidedly depressed mentally. He threatened suicide and on the day before death, exactly three months after discharge from the hospital, attempted to hang

himself. He was admitted to a hospital where he received sedatives. That evening his respirations decreased and his pulse could not be felt. One hour later he developed sudden respiratory paralysis and died.

DIFFERENTIAL DIAGNOSIS

DR RAYMOND D ADAMS. The initial complaint, that of numbness of the left leg, is readily explained by the finding of hypalgesia and thermohypesthesia, both of which are signs of a lesion involving the lateral spinothalamic tract. The progression of the numbness from leg to trunk and upper extremity is possible because of the lamination of the fibers within the lateral spinothalamic tract, the leg fibers which are most lateral being involved first. I do not know how to interpret the unpleasant burning sensations. Since there was no sensory disturbance over the left side of the face, the lesion of lateral spinothalamic tract must have been in the medulla or pons below the point where the ventral trigeminal lemniscus joins the lateral spinothalamic tract. The loss of pain and temperature sensations on the right side of the face and the absent right corneal reflex mean involvement of the spinal tract and the nucleus of the trigeminal nerve. Again this involvement must have been between the mid-pons and medulla oblongata to account for all the divisions of the trigeminal nerve that were affected. This crossed sensory disturbance places the lesion in the medulla or pons on the right side.

The next developments — dysphonia, dysphagia, the absent right gag reflex and palatal deviation to the left — signify involvement of the right nucleus ambiguus, which lies just medial to the lateral spinothalamic tract. Singultus is a respiratory reflex and undoubtedly of central origin in this case, presumably from a disturbance in some of the connections of vagus nerve, such as the nucleus of the tractus solitarius or the nucleus intercalatus. These additional findings locate the lesion in the medulla, more specifically in the retro-olivary region.

Unsteadiness of gait with deviation to the right and inco-ordination of movements of the right arm and leg are cerebellar signs. In this case they were probably due to interruption of the right spinocerebellar tracts. The tracts are just lateral and dorsal to the lateral spinothalamic tract, the spinal nucleus and the tract of the trigeminal nerve.

Slight miosis of the right pupil was observed, but the other components of Horner's syndrome are not mentioned. Pupillodilator fibers from the hypothalamus to the cervical spinal cord (descending sympathetic tract) pass through the reticular

substance of the medulla very close to where the lesion appears to have been. This tract is uncrossed, hence the ipsilateral sign.

Nausea, vomiting and vertigo, without tinnitus or deafness, can only mean a central vestibular disturbance. The spinal vestibular nucleus and its connection with the dorsal motor nucleus of the vagus afford a ready explanation of these symptoms. The rotary nystagmus is on this basis.

The loss of pain and temperature sensations on the left side of the face makes us think of a lesion of the ventral trigeminal lemniscus tract after it has crossed. This tract originates in the nucleus of the spinal tract of the trigeminal nerve and decussates almost immediately, coming to lie along the ventromedial portion of the medial lemniscus in the upper pons it joins the lateral spinothalamic tract and continues to the ventral nucleus of the thalamus. Thus, the lesion extended medially and interrupted this tract after it had decussated.

Another indication of a medial extension of the lesion was the atrophy and fibrillation of the tongue. This is caused either by destruction of the right hypoglossal nucleus or the fibers of this nucleus as they course ventrally toward the pyramidal tract.

The weakness of the right arm and leg, which was observed only once and then without reflex changes, I shall place in the group of cerebellar signs, there is no evidence of pyramidal-tract disease. The facial weakness was too uncertain to consider seriously. The depressed mood which led to his suicidal attempt I cannot put on a neurological basis. Lesions of the posterior hypothalamus are associated sometimes with apathy, drowsiness and depression, but here it is safer to consider the depression as a reaction to an incurable disease. The right occipital headaches confirm the lateralization, which is well established; they are not a sign of increased intracranial pressure.

From these data I think we can be sure of a single lesion in the right tegmentum of the medulla oblongata at about the level of the olive, involving, in order, the lateral spinothalamic tract, the spinal nucleus and tract of the trigeminal nerve, the nucleus ambiguus, the dorsal and ventral spinocerebellar tracts, the nucleus solitarius and its tract, the spinal vestibular nucleus, the dorsal motor nucleus of the vagus nerve, the ventral trigeminal lemniscus and the hypoglossal nucleus.

There occur to me five possible causes of such a lesion. An occlusion of the right vertebral and right posterior inferior cerebellar artery produces a retro-olivary syndrome. The gradual onset and progression of symptoms is unlike a vascular lesion, due either to hemorrhage or to thrombosis. Also

the lingual atrophy and the loss of pain and temperature fibers from the opposite side of the face are not parts of this syndrome, so more than one vessel would have to be occluded.

Tuberculoma must always be considered in a progressive lesion of the medulla, pons or cerebellum. There is not sufficient positive information, such as signs of pulmonary tuberculosis, fever and leukocytosis, on which to make such a diagnosis, but it cannot be excluded.

Syringobulbia is a diagnosis which must be mentioned in passing chiefly because it sometimes produces lesions in this region of the central nervous system. However, rapid progress of the lesion and an early fatal termination are unusual, and the lesion in this case appears to be too discrete. I cannot dismiss this diagnosis with certainty but consider it less likely than those which follow.

Acute multiple sclerosis or encephalomyelitis, a disease entity which most neuropathologists prefer to separate from ordinary multiple sclerosis, is a possibility. However, the onset of symptoms and signs is more acute and the remissions are more certain than any which were found in this case. Particular attention is called to the statement that although there was improvement in some of the signs none of the important ones ever disappeared. If a single sign had completely cleared up, even after roentgen therapy, we should probably have to consider acute multiple sclerosis as the most likely diagnosis. The fact that the signs point to a solitary lesion and not to disseminated ones is also against this diagnosis.

The most probable cause of this clinical picture is an intramedullary glioma. The insidious onset, the slow progression of symptoms, and the manner in which adjacent tracts and nuclei were involved all favor this diagnosis. As to the type of tumor, we can only guess, spongioblastoma multiforme, spongioblastoma polare and astrocytoma are the commonest. We have no reason to suspect a lymphoma or a metastasis of a tumor elsewhere in the body. The laboratory data are of no help. Evidently the attending physician also diagnosed tumor and prescribed x-ray treatment. Signs of increased intracranial pressure occur late in brain stem tumors and are not necessary for the diagnosis of a tumor of the medulla.

The patient died of respiratory failure. Whether the hanging or the sedation were contributory factors I cannot say; the lesion itself probably was sufficient.

CLINICAL DIAGNOSIS

Encephalomyelitis?

DR ADAMS'S DIAGNOSIS

Glioma of right tegmentum of medulla oblongata.

ANATOMICAL DIAGNOSIS

Glioblastoma multiforme of medulla

PATHOLOGICAL DISCUSSION

DR CHARLES S KUBIK Dr Adams has made a very good analysis of the symptoms and findings, and his diagnosis is correct both as to the nature of

the lesion and its localization. There was a diffusely infiltrating glioma of the right side of the medulla. It measured from 3 to 4 cm in diameter and involved the whole of the right side dorsal to the inferior olive. It apparently did not extend beyond the midline or into the pons. Microscopically it was a glioblastoma multiforme. The case is rather unusual in that the tumor was restricted to the medulla. Most of the gliomas of the brain stem involve the pons or the pons and midbrain. These too may be, and often are, limited to only one side of the brain stem.

EDUCATIONAL QUALIFICATIONS FOR HEALTH OFFICERS

THE Committee on Professional Education of the American Public Health Association has recently issued a report* in which it discusses the educational background desirable in the training of health officers. The difficulties encountered by this committee must be very like those encountered by the "boards" of the various specialties. It is not easy to maintain a balance between the practices of the past and the theories of the future. In the same breath that they state the optimal educational advantages which should be insisted on they must also admit that the optimal performance at which they aim has been repeatedly achieved by individuals whose educational advantages were de-

ficient if measured by the standards they wish to promulgate. The result is that such committees and boards must tread lightly until they have established themselves and their principles.

In the field of public health it would seem that a few major principles have been established. The first recommendation of the committee is as follows: "That candidates for appointment as health officer should be graduates of approved medical schools who have completed successfully not less than one year of internship in an approved hospital and in addition a course of not less than one year of graduate instruction in a university, leading to a degree in public health." From this it would seem that the medical degree has been accepted as a necessary possession for all who covet a recognized career in public health. This is a significant decision because the field is occupied by a large number of associated professions. It expresses the belief that public health cannot be effectively administered by those who do not understand the language of the medical profession. The same is already true in other fields, such as those of hospital administration, industrial health and the trained varieties of social service.

Thus in many fields the degree of Doctor of Medicine may be utilized as a preliminary attainment beyond which the individual fully intends and is expected to narrow himself into a more limited proficiency. Recently a twenty six year-old nurse anesthetist embarked on a ten year program in order that she might become an anesthesiologist. It is sometimes difficult to know whether our educational systems are preparing their votaries to serve themselves or their fellow men and women, or perhaps they are already too vast to be anything more than gigantic information bureaus. The best of them graduate relatively inexperienced individuals, and this is covered by the second recommendation: "That recognition be given to the fact that practical experience in public health administration is an essential part of the education of a health officer."

A committee formed by the Massachusetts Central Health Council to make inquiry into this subject has recently reported similar difficulties in

*The educational qualifications of health officers. *Am J Pub Health* 1939.

framing suitable standards. This committee however, did uncover a law in Connecticut that requires that county health officers be lawyers! While it is doubtful that public-health law is as yet sufficiently involved to make this a wise requirement, if this or any other provision might ensure good administrative ability on the part of the officer it would, to that extent, have merit. Whereas a competent administrator can readily get technical advice, a competent technician needs more than advice to do a good administrative job.

The superior health officer, anesthetist, hospital superintendent or anyone else will remain the person whose graciousness, personality and intuitive appreciation of what is fitting on all occasions equal or surpass his knowledge of mere technics.

ADVANCES IN CANCER CONTROL

THE American Society for the Control of Cancer and its managing director, Dr. Clarence C. Little, deserve congratulations for the pamphlet* issued by the Public Affairs Committee, entitled *The Fight on Cancer*. It is short and readable, with graphic presentation of figures. The one point that might be objected to is the all too frequent error of overestimating the curability of skin cancer. The familiar figure of 95-per-cent curability in early cancer as against 30-per-cent curability late in the disease is given, whereas careful analysis of large series shows that even in very favorable lesions, and omitting such forms as malignant melanoma, only a little over 90 per cent are curable, and in taking advanced cases, 20-per-cent curability is perhaps a generous estimate.

The section on research in cancer is very clear and useful. One of the most important phases of cancer investigation—the field of radiation therapy—is, perhaps wisely, not touched on in this pamphlet. In Boston, thanks to the efforts of the pioneer radiologists and their successors of the present day, together with an unparalleled cooperation of the departments of physics and of chemistry of Harvard University and the Massachusetts Institute of Technology with the various cancer investigation and treatment centers, there

has developed an armamentarium for the study of the efficacy of radiation therapy that is duplicated nowhere else in the world. With x-ray apparatus ranging from the ordinary therapeutic types through machines of 400,000 to 1,000,000 volts in constant use, with a 3,000,000-volt x-ray machine approaching completion at the Massachusetts Institute of Technology, with an adequate supply of radium and radon, with practically unlimited opportunity for the making of temporarily radioactive compounds through the two great cyclotrons at Harvard University and the Massachusetts Institute of Technology, there is an ideal situation for the development of knowledge along these lines. If radiation therapy does not make great strides in the control of cancer in the next few years, it will not be for lack of personnel or equipment, at least in Boston.

MEDICAL EPONYM

BLAUD'S PILL

Paul Blaud (1774–1858), chief physician of the hospital at Beaucaire and corresponding member of the Royal Academy of Medicine of France, is chiefly remembered for his famous pill, the formula of which was given in an article presented to the Royal Academy of Medicine, August 23, 1831, entitled "Memoire sur les maladies chlorotiques, et sur un mode de traitement spécifique dans ces affections [An essay on the chlorotic affections and a specific method of treatment]." This appears in the *Revue médicale* (1:337–367, 1832). A portion of the translation follows:

Iron has always been used in chlorosis, for which it has been considered a specific, but all practitioners know how uncertain is its effect in this disease, and how often it fails, a failure which results from the feeble doses administered, and from the fact that it is given in an unsuitable form. Modify the iron with regard to the absorbent capacity of the intestines, and, secondly administer it in a sufficient dose. All the condition will then be present for its action on the organism and the effects of this precious metal will be quickly manifest.

The following formula fulfills these essential conditions

| | | | |
|-----------|----|---|-----|
| | Rx | Iron sulfate | ℥ss |
| | | Potassium subcarbonate | ℥ss |
| Pulverize | | separately, mix slowly and carefully | |
| then add | | Tragacanth mucilage | q.s |
| | | Pound up vigorously and make a mass, divide into 48 pills | |

The dosage was two pills daily for three days, three pills daily for three days, four pills daily for

*Little C. C. The fight on cancer. Public Affairs Pamphlets No. 38. 31 pp. New York: American Society for the Control of Cancer, 1939.

three days, thereafter, twelve pills daily until well. Each pill contained 5 gr (0.3 gm) of iron sulfate. Twelve contained 60 gr (4 gm), a daily dose which compares favorably with that recommended by the most recent advocates of large doses of iron in secondary anemia.

He reported thirty cases

SEPSIS FOLLOWING CESAREAN SECTION FOR PARTIAL SEPARATION OF THE PLACENTA

Mrs. E., a thirty-three year-old primipara at term was sent into the hospital for the purpose of induction on October 27, 1932. Before this was done the patient had soaked two pads with bright red blood and passed some clots.

The family history was non-contributory. The patient had had scarlet fever and measles as a child, the appendix had been removed in 1920 and the operation had been followed by pneumonia. The tonsils had been taken out twice, and the patient had had arthritis in the hands. Curettage and cervical dilatation for sterility had been performed in 1931. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted five days. The last period began January 17, making the expected date of confinement October 24. The pregnancy had been uneventful.

At entry, the uterus was not relaxed and the fetal heart was heard. It was evident that she had a partial separation of the placenta and a cesarean was decided upon. This was performed under nitrous oxide, oxygen and ether anesthesia, and a male child, weighing 8 pounds, 1 ounce, was delivered in good condition.

On October 28, the day following the operation, the afternoon temperature was 102°F and rose during the evening to 104°. The next afternoon it went to 105°F following a chill. On October 30 the morning temperature was 103°F, and the pulse 120. The abdomen was soft, and there was some distention. A medical consultation revealed nothing in the chest. The patient ran an irregular temperature for ten days, ranging from 100 to 104°F in the afternoon. During this time she

drained large amounts of thick, foul smelling lochia. The abdomen was negative, and there was no nausea or vomiting. Although no cultures were taken from the uterus, she undoubtedly had uterine sepsis. Toward the end of the infection a mass developed on the left, almost at the level of the anterior superior spine. She was discharged on November 16, completely well.

When seen on December 8, the mass had entirely disappeared.

Comment. This is a case of uncomplicated uterine sepsis following a clean cesarean section. There was no evidence of peritonitis at the time of operation. The etiology of the infection is unknown as no blood or uterine cultures were taken. The treatment was entirely conservative; the uterus was left alone, and only supportive treatment was administered.

TREASURER'S REPORT

COVERING REFUND DISTRIBUTION

The Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to the district societies for 1940.

The Council voted to distribute the sum of \$5000 to district societies. The total number of payments of annual dues received by the Treasurer by March 4, to be counted for the refund, was 4058. There fore the refund to the district societies for each paid fellow is \$1.232.

The following table gives the number of payments in, and the refund to, each district, as of March 26.

| DISTRICT | NUMBER REPORTED PAID | REFUND |
|-----------------|-------------------------|-----------|
| Barnstable | 47 | 58.00 |
| Berkshire | 109 | 134.29 |
| Bristol North | 56 | 69.10 |
| Bristol South | 159 | 195.89 |
| Essex North | 175 | 215.60 |
| Essex South | 223 | 274.74 |
| Franklin | 39 | 48.18 |
| Hampden | 296 | 364.67 |
| Hampshire | 57 | 70.32 |
| Middlesex East | 109 | 134.29 |
| Middlesex North | 113 | 139.22 |
| Middlesex South | 813 | 1001.62 |
| Norfolk | 721 | 888.27 |
| Norfolk South | 107 | 131.82 |
| Plymouth | 115 | 141.68 |
| Suffolk | 500 | 616.00 |
| Worcester | 341 | 420.11 |
| Worcester North | 78 | 96.20 |
| | 4058 | \$5000.00 |

In 1939 for comparison, the total number of payments for the refund was 3916.

CHARLES S. BUTLER, M.D., *Treasurer*

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 7

BERKSHIRE

Thursday, April 11, at 4 30 p.m., at the Bishop House of Mercy Hospital, Pittsfield. Complications in Obstetrics Illustrated by case histories. Instructor Robert L. DeNormandie. Harry G. Mellen, *Chairman*

BRISTOL SOUTH (Fall River Section)

Tuesday, April 9, at 4 30 p.m., at the Union Hospital, Fall River. Head and Spine Injuries. Instructor Walter R. Wegner. Howard P. Sawyer, *Chairman*

FRANKLIN

Thursday, April 11, at 8 15 p.m., at the Franklin County Hospital, Greenfield. Head and Spine Injuries. Instructor Donald Munro. Halbert G. Stetson, *Chairman*

HAMPDEN

Thursday, April 11, at 4 00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 15 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Gonorrhea in the Female. Instructor Oscar F. Cox, Jr. George L. Schadt, *Chairman*

HAMPSHIRE

Thursday, April 11, at 4 15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton. Cardiovascular Disease. Eleven important questions about heart disease and their answers. Instructor R. Earle Glendy. Warren P. Cordes, *Chairman*

MIDDLESEX SOUTH

Tuesday, April 9, at 4 30 p.m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Common Problems of Neurology. Indications for lumbar puncture. Instructor H. Houston Merritt. Dudley Merrill, *Chairman*

NORFOLK

Thursday, April 11, at 8 30 p.m., at the Norwood Hospital, Norwood. Common Problems of Neurology. Indications for lumbar puncture. Instructor H. Houston Merritt. Hugo B. C. Riemer, *Chairman*

Thursday, April 11, at 4 30 p.m., in John Ware Hall, Boston Medical Library, 8 Fenway, Boston. Pneumonia. Instructor Maxwell Finland. Reginald Fitz, *Chairman*

DEATHS

BAILEY—GEORGE G. BAILEY, M.D., of Ipswich, died March 30. He was in his seventy-sixth year.

He received his degree from the Harvard Medical School in 1892. Dr. Bailey was a fellow of the Massachusetts Medical Society and the American Medical Association and was a member of the staff of the Cable Memorial Hospital, Ipswich. He had recently resigned his position as medical examiner, which he had held for forty-two years, because of ill health.

His widow, a son, Dr. George G., Jr., and two daughters survive him.

MARSHALL—AUGUSTUS T. MARSHALL, M.D., of Randolph, Vermont, died recently. He was in his sixty-fifth year.

Dr. Marshall received his degree from Dartmouth Medical School in 1901 and was a fellow of the Massachusetts Medical Society and the American Medical Association.

SMITH—FORSTER H. SMITH, M.D., of Lowell, died recently. He was in his sixty-fourth year.

Dr. Smith received his degree in 1902 from the Harvard Medical School. He was former superintendent of the Lowell Isolation Hospital, and a former member of the Massachusetts Medical Society.

His widow and a son survive him.

MISCELLANY

MAINE NEWS

REMOVAL NOTICES

The following removal notices have been received: George W. R. Bowie, M.D., from New Gloucester to Vanceboro.

E. Allen McLean, M.D., from 201 State Street, to 29 Deering Street, Portland.

MAINE MEDICAL ASSOCIATION

The following physicians have been recently admitted to membership in the Maine Medical Association:

Ernest L. Coffin, M.D., Northeast Harbor
Henry Almond, M.D., Gardiner
Wilfred J. Comeau, M.D., Bangor
Paul A. Millington, M.D., Newport
John Valentine, M.D., Dover-Foxcroft
Willis B. Mitchell, M.D., Wiscasset

CORRESPONDENCE

AUSTEN FOX RIGGS

To the Editor—In the *Journal* of March 14, 1940, the death of Austen Fox Riggs of Stockbridge was announced.

I should like to take this opportunity of paying tribute to a physician whose professional career was as striking as the gallant conduct of his life. Dr. Riggs had pre-

pared himself for the practice of internal medicine and had been assistant to Dr. Walter B. James of New York City for three years when conditions of health made it advisable for him to leave New York City and to take up residence in the Berkshires. There for over thirty years and frequently despite personal ill health he devoted himself to his chosen field of work—the treatment of nervous patients burdened with personal difficulties, unable to deal unaided with problems of life. In this task he was peculiarly successful. He gathered around him a group of able young associates, he kept abreast of medical progress, and he considered earnestly the objective appraisal of his work by his medical colleagues. Not satisfied with the mere exercise of his professional skill he carefully analyzed methods and results in the attempt to formulate general principles. Before his death he had the satisfaction of seeing in manuscript form a critical statistical analysis of his life work. Dr. Riggs emphasized the value of his chosen psychotherapeutic methods, and was somewhat impatient with the suggestion that his results depended more on his unusual personal influence than on the special methods he employed. His patients could not but be influenced by his sincerity, sympathy and optimism and by his imposing presence.

As a consultant he was held in high value by colleagues and hospitals. His many interests were indicated by the large number of organizations with which he was affiliated. He inspired a deep affection among an unusual number of friends.

The medical profession has lost a member of unusual value, the community a wise adviser and he leaves his widow and four children a precious memory.

C. MACFIE CAMPBELL.

74 Fenwood Road
Boston.

DONATIONS OF BOOKS AND PERIODICALS

To the Editor: I have had urgent requests for books and periodicals from both China, where the disruption of hospitals and medical schools has made difficult the securing of medical literature, and also from refugees in Mexico who have wholly lost their libraries and their contact with recent literature. If readers of this note should have spare copies of books or periodicals which they would be willing to contribute to either China or Mexico, may I ask that they send them to Miss Anna C. Holt, Librarian Building A, Harvard Medical School. If donors prefer that their gifts be sent to one country or the other they should indicate their preference.

WALTER B. CANNON

25 Shattuck Street
Boston, Mass.

REPORT OF MEETING

GREATER BOSTON MEDICAL SOCIETY

A regular meeting of the Greater Boston Medical Society was held on January 2 at the Beth Israel Hospital. Dr. Max Ruto introduced Dr. Abraham Myerson, who spoke on "Recent Advances in the Treatment of Epilepsy and Schizophrenia."

Dr. Myerson explained that these two seemingly diverse conditions were being considered together because of the suggestive similarity in brain waves and because schizophrenia has recently been treated by the induction of epileptiform convulsions.

The first consideration was epilepsy which was defined as a periodic loss or impairment of consciousness, with or without associated convulsions. In the grand-mal type of seizure there are convulsions, whereas the attacks of petit mal merely result in temporary unconsciousness. An additional type of epilepsy called by Gibbs and Lennox the "psychomotor attack," is characterized by organized motions in the unconscious state.

The speaker cited various factors which appear to influence the incidence of attacks in a susceptible person. Their occurrence during sleep as well as during the periods of falling asleep and awakening has long been observed and has more recently been related to the similarity of the electroencephalographic tracings of the sleeping person and epileptic. The incidence of seizures during organic disease of the central nervous system is greater than can be expected by chance. The fact that drugs such as Metrazol induce convulsions has been the basis of the recent shock treatment of schizophrenia. Hyperventilation and indeed alkalosis of any sort, favors the onset of attacks and the favorable effects of acidosis were the basis of the formerly employed ketogenic diet in the treatment of epilepsy. Further studies serve to indicate that cerebral dehydration and an elevated blood sugar are also beneficial in this condition.

One of the great advances in the study of the mechanism of epilepsy was the introduction by Berger in 1929 of the electroencephalogram, which has subsequently been elaborated and its findings extensively interpreted by Lennox and Gibbs. The latter workers have insisted on the recognition of the underlying paroxysmal cerebral dysrhythmia. They maintain that epilepsy is in reality a chronic disorder with clinical manifestations other than the abnormal electroencephalogram, observed only during periodic "explosions." Similar tracings during sleep show bursts of activity very suggestive of epilepsy and the resemblance of these cerebral dysrhythmias to those of the respiratory system was suggested by Dr. Myerson. Clinical evidence and brain-wave tracings corroborate the fact that voluntary effort, either mental or physical aids in warding off an incipient epileptiform seizure—a fact that most patients soon learn empirically.

Dr. Myerson showed typical electroencephalographic charts of Lennox and Gibbs, which demonstrated the increasing frequency and irregularity of waves during a grand-mal seizure and the characteristic wave and spike of the petit mal attack, coming in bursts in both instances, even in the absence of clinical signs or symptoms. The findings during a psychomotor attack were not considered so constant by Dr. Myerson. Characteristically there is a slow plateau type of wave, which Lennox and Gibbs have found very similar to some tracings in schizophrenic patients. Another well-known observation resulting from the extensive use of electroencephalograms by Gibbs and Lennox was the greater incidence of pathologic wave tracings in relatives of epileptic patients than in the population at large but no exact correlation has been proved to exist between abnormal waves and clinical manifestations of epilepsy.

Dr. Myerson concluded his discussion of epilepsy with a résumé of the development of therapy and an appraisal of its present status. Sedatives had long ago proved their efficacy but the bromides, which were first used produced toxic symptoms when employed in sufficient quantities to minimize the convulsions. Phenobarbital was then used with commendable results, particularly in relatively large doses for grand-mal seizures. Then the researches of Putnam and Merritt showed the phenyl group to be the important constituent of the barbiturates and resulted in the

introduction of the new drug, Dilantin (diphenyl hydantoin). This is largely free of the unpleasant and occasionally dangerous sedative effects of the barbiturates and has proved at least promising in therapy. For the past three years, Dr. Myerson and his collaborators have endeavored to assay the value of various therapeutic agents in the treatment of 150 patients at the Grafton State Hospital. One group has received greatly increased doses of the barbiturates, with stimulants when necessary to allay the sedative effects. Another group received Dilantin, a third group Dilantin and ordinary doses of phenobarbital, while the last group received another new drug, Meborol. The first group showed 65 per cent decrease in number of seizures, while the third group had a reduction of 85 per cent, with the greatest value being exhibited in the grand mal type of seizure. The two newer drugs alone, on the other hand, showed their greatest effect in the petit-mal and psychomotor attacks and were much less prone to cause depressing toxic effects. On the whole, Dr. Myerson concluded that the prognosis for epilepsy was now far from hopeless.

The speaker then continued with a discussion of schizophrenia, pointing out that this condition is now known to have an acute form and may exhibit spontaneous reversals, so that it is not necessarily a chronic and hopeless disease as formerly believed. The facts that Amytal and amphetamine have been demonstrated to cause a temporary remission and that insulin and Metrazol therapy have "produced" remissions of longer or shorter duration serve to indicate that drug therapy may eventually solve the problem. The results so far, however, have failed to attain the success originally predicted.

Dr. Myerson described his "total push" method for helping these unfortunate patients. This was based on the concept that these patients were not aided but rather hindered by the superimposition of a prison psychosis on their fundamental imbalance. Therefore it was decided to interest the patients in physical and mental exercises and to offer praise or blame, reward or punishment, where it was merited. The patients chosen were those who had been sick for over ten years and who had had no remissions. These people have now been treated for more than a year, and although no claims can be made for cures, several patients have improved sufficiently to be released from the institution, for all or part of the time. It was concluded, therefore, that the main problem at present in treating schizophrenia in the absence of a specific drug was to abolish defeatism among the medical profession.

The discussion was inaugurated by Dr. William G. Lennox, who stated that the incidence of abnormal electroencephalograms among essentially normal persons as well as among asymptomatic relatives of epileptic patients had put emphasis on the significance of the fundamental dysrhythmia rather than on the occurrence of seizures. Ten per cent of supposedly normal people exhibit persistent changes in their brain waves, while the incidence in relatives of epileptics is eight times normal. The problem, then, is to determine who are going to have symptomatic manifestations. Dr. Lennox stated that there is probably a change of the arterial carbon dioxide content to an elevated level in grand mal and to a lowered level in petit-mal seizures. The results with Dilantin at the Boston City Hospital have not been so good in petit-mal attacks as have been those of Dr. Myerson, and it was believed that this was the result of better diagnosis which put some of these cases in their true category of psychomotor disturbances where this drug is particularly efficacious.

Dr. H. Houston Merritt discussed, with diagrams, the rationale of the development of the newer phenyl derivatives and expressed the hope that a truly specific drug might be forthcoming.

Dr. Kenneth J. Tillotson emphasized the value of electroencephalogram in mental institutions, particularly in regard to schizophrenia. At the McLean Hospital the 11 worst schizoid patients chosen for Dr. Myerson's total push method have left the hospital, while 8 remaining 9 have shown tremendous improvement. A total of 75 persons so treated, some following unilateral shock therapy, many have left the hospital and a majority have shown immeasurable gain.

Dr. Harry C. Solomon mentioned the American method of treating schizophrenic patients as psychological rather than as organic problems, but said that there was some of each factor playing a role. Although the incidence of abnormal electroencephalographic findings is higher in these people than in the population at large, the fact that some ostensibly normal individuals have abnormal findings than do many schizoid patients leads to any conclusions as to the nature of the condition. The speaker warned that in the appraisal of therapy, one should always be cognizant of the 20 per cent of spontaneous cures with little or no damage. Dr. Solomon concluded by lauding the total push system for enabling schizophrenia to be studied out of any complicating institutional psychosis and for opening the profession to the possibilities of treatment of this disease.

Dr. Wilfred Bloomberg stated that the original conception of schizophrenia included a hopeless prognosis that cures made the diagnosis untenable. He has observed in prisons that long term inmates often develop a condition surprisingly similar to a simple schizophrenia, and they prefer to return to the seclusion of Charlestown Prison rather than to remain at the Norfolk Farm, where forward looking criminologists attempt a regimen like that of Dr. Myerson. Dr. Bloomberg was of the opinion that some schizoid patients, therefore, are better off in prison than they are in being brought to face what they have been fleeing.

NOTICES

BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday, April 11, at 12 o'clock noon, in the Pathological Amphitheater.

BOSTON LYING IN HOSPITAL

The Journal Club will hold its next meeting in the lecture hall of the Boston Lying in Hospital on Tuesday, April 16, at 8:15 p.m. Dr. Abraham Myerson will discuss "The Heredity of Mental and Nervous Disease: Eugenical Sterilization."

Physicians and students are cordially invited to attend.

HOSPITAL COUNCIL OF BOSTON

The annual meeting of the Hospital Council of Boston will be held at the New England Deaconess Hospital on Tuesday, April 9, at 12:30 noon. Action will be taken on the applications of the Boston Lying in Hospital and Cambridge Hospital for membership.

PROGRAM

Convalescence and the Nursing Home Information Bureau. Miss Carrie M. Hall.

Mr. Frank E. Wing will report on the following:

Should the New England Hospital for Women and Children Increase its Obstetrical Facilities?

Is There Need for Outpatient Facilities at the New England Baptist Hospital?

City Responsibility for Reimbursement for Care of Relief Clients in Voluntary Hospitals, Salaries.

Legislation. Dr Charles F Wilinsky

Members of the medical profession are cordially invited to attend. The charge for luncheon will be 75 cents. Reservations should be made before April 6 (LIB 8515)

BOSTON DOCTORS SYMPHONY ORCHESTRA

The first concert of the Boston Doctors Symphony Orchestra, Alexander Thiede, conductor will be held at 8 15 on Sunday evening, May 5 at Jordan Hall. Tickets are priced at one dollar

and the proceeds will be given to a medical charity. The ticket committee is composed of Dr. Welman B. Christie, chairman, 15 Bay State Road, Boston, Dr. Julius Loman, 1284 Beacon Street, Brookline, and Dr. Robert G. Vance, 262 Beacon Street, Boston.

SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday April 16, at 12 o'clock noon. Dr. Edward D. Churchill will speak on "Surgery of the Lungs."

Physicians are cordially invited to attend.

PETER BENT BRIGHAM HOSPITAL

A research conference of the medical staff of the Peter Bent Brigham Hospital will be held in the amphitheater of the hospital on Tuesday April 9 at 5 00 p.m.

PROGRAM

Experiments with the Miller Abbott Tube and Chemistry of the Jejunal Juices. Drs. Lemuel C. McGee and E. S. Emery Jr.
Observations on the Effect of Salyrgan on Blood Volume. Dr. Reginald Fitz.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday April 10 from 7 to 4 p.m. Drs. E. C. Cutler and Soma Weiss will speak on "The Unconscious Patient."

Physicians and students are cordially invited to attend.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday April 9 in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance) at 8 15 p.m. Dr. Soma Weiss will preside.

PROGRAM

Experimental Observations on the Physiology of Shock. Dr. John G. Gibson, 2nd.
Observations on the Pathology of Shock. Dr. John E. Dunphy.
Clinical Aspects of Shock. Dr. Eugene A. Stead, Jr.
Medical students and physicians are cordially invited to attend.

SIR WILLIAM OSLER HONORARY SOCIETY

The annual lecture of the Sir William Osler Honorary Society of the Tufts College Medical School will be given by Dr. Chester S. Keefer on Friday evening, April 26, at 8 00 in the Beth Israel Hospital Auditorium Boston.

Dr. Keefer will speak on "The Clinical Interpretation of Bacteremia."

MASSACHUSETTS DEPARTMENT OF CIVIL SERVICE AND REGISTRATION

SCHOOL INSPECTOR, BOARD OF HEALTH \$600 A YEAR, EVERETT

Director of State Civil Service, Ulysses J. Lupien has announced that competitive examinations are to be held on April 26 in order to find eligibles for appointment to the position of School Inspector Board of Health Everett.

The entrance requirement is as follows: applicants must be registered physicians under the State Board of Registration in Medicine. The subjects and weights of the examination are as follows: training and experience, 2 practical questions, 3 total, 5. Applicants must obtain a grade of 70 per cent in each subject in order to become eligible. The last date for filing applications is Friday April 12, at 5 00 p.m.

MEDICAL INSPECTOR (MALE) \$700 A YEAR, SPRINGFIELD

Director of State Civil Service, Ulysses J. Lupien has announced that competitive examinations are to be held on May 4 in order to find eligibles for appointment to the above position.

The entrance requirement is as follows: applicants must be registered physicians under the State Board of Registration in Medicine. The subjects and weights of the examination are as follows: training and experience, 2 practical questions, 3 total, 5. Applicants must obtain a grade of 70 per cent in each subject in order to become eligible. The last date for filing applications is Saturday April 20 at 12 o'clock noon.

NEW ENGLAND PATHOLOGICAL SOCIETY

The next meeting of the New England Pathological Society will be held at the Peter Bent Brigham Hospital on Thursday April 18 at 8 00 p.m. Dr. Hamilton Montgomery a member of the Section on Dermatology Mayo Clinic will speak on the subject "Pathologic Features of Some of the Non-neoplastic Dermatoses."

Physicians and medical students are cordially invited.

NEW ENGLAND DERMATOLOGICAL SOCIETY

The annual meeting of the New England Dermatological Society will be held on Wednesday April 10 at 2 00 p.m., at the Boston City Hospital. At 5 00 p.m., Dr. Alan R. Montz will speak on "Accident, Murder or Suicide?" Following the meeting, dinner and entertainment will be held at the Hotel Kenmore.

NEW ENGLAND OTO-LARYNGOLOGICAL SOCIETY

The regular spring meeting of the New England Otolaryngological Society will be held at the Massachusetts

Eye and Ear Infirmary, 243 Charles Street, Boston, on Wednesday, April 10, at 4 00 p.m.

PROGRAM

- 4 00 p.m. Presentation of hospital cases Dr LeRoy A Schall and infirmary staff
 Acute Surgical Mastoiditis Following Fracture of the Skull Dr Herman Winkler, Providence, Rhode Island
 Bronchial Asthma Due to Bacterial Allergy Dr Warren Kershner, Bath, Maine.
 Osteomyelitis of the Frontal Bone Dr Adolphe Provost, Manchester, New Hampshire.
 Complications of a Parapharyngeal Abscess Dr Louis M Freedman
 Preventing the Chronic Running Ear Dr Harry Goodspeed, Worcester, Massachusetts
 6 30 p.m. Buffet supper
 7 45 p.m. Business meeting
 8 00 p.m. Chemotherapy of Otitis Media. Dr Champ Lyons Discussion Drs Robert N Ganz and Carl H Ernlund

NEW ENGLAND INSTITUTE OF HEALTH

The New England Health Institute will be held in Hartford, Connecticut, the entire week of April 15-19. The headquarters and all lectures will be at Hotel Bond, 320 Asylum Street. Registration will begin Monday morning, April 15, at nine o'clock and will continue through the week. A fee of one dollar will be charged to cover routine expenses.

The lectures will begin at 2 p.m., Monday afternoon, and four lectures will be given simultaneously each hour, from 9 30-12 30, and from 2 00-5 00. Signals will be given five minutes before each hour so that each lecture will close promptly and the next lecture begin on time. Lectures are open to all those who are interested in public health or actively engaged in the work. The various sections and chairmen are as follows:

| SECTION | CHAIRMEN |
|-----------------------|---------------------------|
| Public-Health | |
| Administration | John A. Ferrell, M.D. |
| Preventable Diseases | Wilson G. Smillie, M.D. |
| Sanitary Engineering | Roscoe H. Suttie, C.E. |
| Vital Statistics | Halbert L. Dunn, M.D. |
| Laboratory | Elliott S. Robinson, M.D. |
| Venereal Diseases | R. A. Vonderlehr, M.D. |
| Industrial Hygiene | R. R. Sayers, M.D. |
| Cancer | C. L. Larkin, M.D. |
| Tuberculosis | David R. Lyman, M.D. |
| Child Hygiene | Martha M. Eliot, M.D. |
| Crippled Children | R. C. Hood, M.D. |
| Nutrition | George R. Cowgill, Ph.D. |
| Public-Health Nursing | Mary D. Forbes, R.N. |
| Mental Hygiene | Eugene Kahn, M.D. |
| Health Education | Clair E. Turner, Dr. P.H. |
| Milk, Food and Drugs | E. G. Woodward, A.M. |

On the evening of Tuesday, April 16, a dinner for the faculty of the Institute will be held at Hotel Bond. A minimum charge will be made for this event. This will be the high spot in the program.

Health moving pictures will be shown daily from 5 00-6 00.

Those desiring detailed information should apply to the State Department of Health, Hartford, Connecticut.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The general oral and pathological examinations (Part II for all candidates (Groups A and B) will be conducted at Atlantic City, New Jersey, from Friday, June 7, through Monday, June 10, prior to the opening of the annual meeting of the American Medical Association in New York City on Wednesday, June 12. Formal notice of the exact time and place of the examination will be forwarded to each candidate several weeks in advance of the examination dates. Group A candidates will be examined on June 7 and 8, and Group B candidates on June 9 and 10.

Candidates for re-examination in Part II must make written application to the Secretary's Office before April 1.

The annual dinner of the board will be held in New York City on Wednesday evening, June 12, at the Hotel McAlpin. Diplomates certified at the preceding day's examinations will be introduced personally, and there will be several speakers. All diplomates of the board, and others interested in the work of the board, are cordially invited to attend this dinner.

Tickets at \$3.50 each may be obtained from Dr. Joseph L. Baer, chairman, 104 S. Michigan Avenue, Chicago, Illinois, or at the registration desk during the examinations.

For further information and application blanks, address Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, APRIL 7

TUESDAY APRIL 9

- *9-10 a.m. Studies on Purpura in Relation to the Spleen and Bone Marrow Dr. William Dameshek Joseph H. Pratt Diagnostic Hospital
 *12 30 p.m. Hospital Council of Boston New England Deaconess Hospital
 5 p.m. Research conference of the medical staff Peter Bent Brigham Hospital amphitheater
 *8 15 p.m. Harvard Medical Society Peter Bent Brigham Hospital (Shattuck Street entrance)

WEDNESDAY APRIL 10

- *9-10 a.m. Hospital case presentation Dr. S. J. Thannhauser Joseph H. Pratt Diagnostic Hospital
 12 m. Monthly clinicopathological conference. Boston City Hospital Pathological amphitheater
 2 p.m. New England Dermatological Society Boston City Hospital
 *2-4 p.m. The Unconscious Patient Drs. E. C. Cutler and Som Weiss Peter Bent Brigham Hospital
 4-8 p.m. New England Oto-Laryngological Society Massachusetts Eye and Ear Infirmary 243 Charles Street Boston

THURSDAY APRIL 11

- *9-10 a.m. Diagnostic Errors Dr. H. G. Brugsch Joseph H. Pratt Diagnostic Hospital

FRIDAY APRIL 12

- *9-10 a.m. Prothrombin and Vitamin K Dr. E. L. Lozner Joseph H. Pratt Diagnostic Hospital

SATURDAY APRIL 13

- *9-10 a.m. Hospital case presentation Dr. Thannhauser Joseph H. Pratt Diagnostic Hospital

*Open to the medical profession

Meetings begin with a dinner at 6:30 p.m. and are followed by business and scientific meetings.

BOOK REVIEWS

Synopsis of Pediatrics. John Zaborsky and T. S. Zahorsky.
 Third edition. 430 pp. St. Louis: C. V. Mosby Co., 1939. \$4.00.

To compress the whole of pediatrics—feeding, growth and hygiene, as well as diseases—into a pocket size volume of 400 pages is no easy task, but the Drs. Zaborsky have succeeded in so doing. Naturally the consideration of particular matters is brought down to the irreducible minimum, but the information furnished though skeletonized, covers all the essential ground. The book is conservative in tone but has been brought entirely up to date. The mere fact that it has passed through three editions in something like six years is proof that it is serving a useful purpose. It should, however, be of more use to the practitioner to whom pediatrics is only an incidental part of practice; the pediatrician has or ought to have most of his material at his fingertips. It may also be recommended

to the medical student who wishes to check up or refresh his memory. As books go it is of excellent value.

Facts and Theories of Psychoanalysis. Ives Hendrick.
 Second edition. 369 pp. New York: Alfred A. Knopf, 1939. \$3.00.

As this excellent survey brings up to date all the new developments in psychoanalysis it is a source of satisfaction that it has now gone into a second revised and enlarged edition. It fulfills the demand due to the increased interest in the scientific aspects of psychoanalysis by psychiatrists and the general medical profession. The book is a basic one and provides an accurate text for a sound understanding of psychoanalysis. The author correctly emphasizes that, in the five years that have elapsed since the appearance of the first edition, there have been no discoveries which have refuted the basic theoretical and practical principles of psychoanalysis.

The volume is divided into four sections: the basic facts of analysis; its theories; analytic therapy and the various medical and other professional applications of the psychoanalytic movement. Among the additions to this revised edition are a discussion of the psychology of female sexuality; recent data on the therapeutic results of psychoanalysis from the Berlin, London and Chicago institutes; an amplification of the previous brief discussion on child analysis; an extended consideration on the psychology of organic disease (psychosomatic reactions); the cultural aspects of psychoanalysis; sections on the systematic training of psychoanalysts as carried out by the various training institutes; suggestions for further reading and a fairly complete glossary of psychoanalytic terms.

There are several features of the volume to which the reviewer would like to call particular attention. The first of these is an account of the two-year investigation of psychoanalysis by a special committee of the British Medical Association subsequently published in the *British Medical Journal*. This special committee concluded that the term "psychoanalysis" can be applied only to the methods and theories evolved by Freud. The section on the recent therapeutic results of psychoanalysis already referred to is of particular interest to the medical profession. Several features are pointed out with which analysts and analytically trained psychiatrists would agree. For instance, cures of symptoms alone are never regarded as significant, the goal of analytic therapy being an adjustment to the problems of life, an adequate strengthening in handling the crippling and suffering symptoms of a neurosis and an increase in capacity of the patient's potentialities.

On the whole, the volume epitomizes the science of psychoanalysis as it is understood today and is therefore of decided value to students, social workers, physicians and psychiatrists.

Psychopathia Sexualis: A medico-forensic study. Richard von Krafft-Ebing. Twelfth edition. 626 pp. New York: Pioneer Publications, Inc., 1939. \$3.00.

This is an inexpensive edition of a standard work on sexual pathology. It is an English translation from the twelfth German edition of 1903 and this translation was first published in 1906. It is now reissued with an introduction and an appendix by Victor Robinson of New York City. The appendix of a little more than eight pages briefly discusses psychoanalysis, endocrinology and the discovery of hormones by Bayliss and Starling and the censorship of sexual literature by the federal authorities. Krafft-Ebing was a pioneer in the field of sexual

pathology and his work went through seventeen editions, the last being issued in Stuttgart in 1924. However, the twelfth edition was the last published from his own manuscript, as he died in 1902, and that edition should be recognized as the authoritative text embodying his latest ideas.

A Textbook of Pathology for Nurses Coleman B Rabin.
Second edition, revised. 260 pp Philadelphia and
London W B Saunders Co., 1939 \$1.75

If we admit that it is desirable for nurses to be subjected to a rather detailed course in pathology and clinical pathology, and if we assume that a good purpose justifies simplification of pathological conceptions, then Dr Rabin has succeeded admirably in fulfilling his purpose. This book follows the plan laid down for the course in pathology given to the students of the Mount Sinai Hospital School of Nursing of New York City. Through twenty-two chapters devoted to pathology the author lays emphasis on the mechanism of disease processes and the correlation of diseased structure with diseased function. Consideration is given the degenerative and inflammatory changes in the body, with special attention to the more important infections, such as tuberculosis and typhoid fever. There is one chapter on ulcers and another on neoplasms. Five chapters are devoted to a consideration of the consequences of obstruction to the viscera. The author has used to good advantage the method originated by MacCallum in the presentation of his material. Four brief well arranged chapters are devoted to clinical pathology. The rather large number of illustrations has been well chosen. In addition diagrammatic representations do much to augment the text.

On the whole the author has not departed from facts in his attempt to simplify the subject. This book should serve as an excellent text for a course in pathology in a nurses' training school.

The Treatment of Rheumatism in General Practice
W S C Copeman Third edition. 276 pp Baltimore
The Williams & Wilkins Co., 1939 \$4.00

The fact that this book is now in its third edition indicates an appeal which your reviewer fails to appreciate. The book is full of traditions, both for diagnosis and treatment, but there is little substantiation. The best explanation for its appeal is that it contains many recommendations for treatment which can be carried out by the general practitioner, though here in New England we should doubt their value. The use of vaccines is recommended, but not justified. Most drugs, except aspirin, are damned with faint praise. Colchicine is not mentioned in the treatment of gout. Atophan and antipyrine are advised, with no mention of their toxicity. Intestinal antiseptics are not recommended, diets are not so simple as they are in the United States, stress is laid on the need of an alkaline ash diet, colonic lavage and medication baths, and spa treatments are given too much prominence. The value of treatment by orthopedists is slighted.

A Textbook of Obstetrics With special reference to nursing care Charles B Reed and Bess I Cooley 476 pp
St. Louis The C V Mosby Co., 1939 \$3.00

For a book which is described as being "brand new," this textbook of obstetrics can hardly be said to be an improvement over the books already published.

The first few chapters, describing anatomy, physiology and embryology, together with that on prenatal care in the normal pregnant woman, are satisfactory. In connection

with many of the complications of pregnancy, however, there are to be found gross errors of commission and omission. In addition, the reviewer could not help noticing many ambiguous statements in which the wording makes the text very difficult to understand. There are many mistakes in spelling throughout the book and these, together with at least one inverted illustration, lead one to infer that the proofreading has been very carelessly done. Consequently, it is difficult to recommend this book.

Teaching for Health Marguerite M. Hussey Second edition 328 pp New York Prentice Hall, Inc., 1939 \$2.25

Miss Hussey is assistant professor of education at New York University, and her work on the relation of teaching to health has required a second edition within a year of its first publication. The book is written from the point of view of the teacher and discusses the factors affecting health which are directly or indirectly controllable by the teacher. Of special interest are the chapters on the relations of the home and parents with the school in the promoting of child health. Under printed materials, standards are set up for evaluating hygienic textbooks. Although the book is primarily a technical manual of methods for promoting the health of the child by the schools, it should prove useful to school physicians and nurses in giving the views of those interested in this type of education.

A Topographic Atlas for X Ray Therapy Ira I. Kaplan and Sidney Rubinfeld 120 pp Chicago The Year Book Publishers, Inc., 1939 \$4.00

This quarto volume consists of fifty five plates, 5 1/4 by 7 inches in size. On the page facing each plate is a concise explanation. The information given by illustrations and text can, of course, be culled from works on topographical anatomy, especially works on surface projections. This volume may serve as a short cut for radiologists or as a guide to technicians. Superficiality is the fellow traveler on all short cuts to fundamental knowledge, this work carries that stigma.

Manual for Diabetic Patients W D Sansum, Alfred E. Koehler and Ruth Bowden. 227 pp New York The Macmillan Co., 1939 \$3.25

The discussion of the nature, diagnosis and dietary treatment of diabetes in this manual is adequate but better suited to the physician than to the patient. In view of the authors' early recommendation of diets containing more liberal quantities of carbohydrate than had previously been used, one naturally turns to their present practice and learns "that we are feeding our adult diabetic patients from 150 to 300 grams and our diabetic children from 100 to 400 grams of carbohydrate daily." Various common complications of diabetes are described and preventive measures recommended. In addition to testing the urine for sugar, it is considered desirable that the patient know how to make the tests for acetone and diacetic acid.

Erratum

In the listing of the book review, *Surgical Applied Anatomy*, by Frederick Treves (*New Eng J Med* 222:334, 1940), the price was given as \$4.00, it should have read \$4.50.

NUMBER 15

ACUTE MECHANICAL OBSTRUCTION OF THE SMALL BOWEL*

Its Diagnosis and Treatment

LELANO S. McKITTRICK, M.D.,† AND S. PETER SARRIS, M.D.‡

BOSTON

IN 1908 Scudder¹ reviewed the cases of acute mechanical obstruction of the small bowel operated on at the Massachusetts General Hospital between 1898 and 1907. Richardson² in 1920 and McIver³ in 1932 reviewed comparable series of cases. This, then, is the fourth report from this hospital. Such a series of reports presupposes a continuity of active interest on the part of the visiting and house staffs in the diagnosis and management of this group of cases, and affords an unusual opportunity for the comparison of the results of treatment over a period of forty years.

Strangulation obstruction was early recognized as the greatest factor in the high mortality of these cases, and the teaching of early diagnosis and early operation has been thoroughly instilled into each and every member of the hospital staff throughout the last thirty years. On the other hand, Scudder,¹ Jones,⁴ Richardson,² McIver³ and others have constantly pointed out the need of accepting the hazards of gangrene in certain cases with late obstruction, and of doing a simple drainage of a distended loop of bowel without exploration as a means of relief.

Monks⁵ in 1905 suggested that a distended loop of bowel could be most satisfactorily emptied by threading it on a glass tube. Wangensteen⁶ in 1931 suggested constant suction applied to an inlying stomach or duodenal tube, and reported 3 cases of acute obstruction which were relieved following this procedure. He, probably more than any other one person, is responsible for the development of the nonsurgical decompression of a distended bowel.⁷⁻⁹ The difficulties of decompressing the lower segment of small bowel through a tube in the upper gastrointestinal tract were well recognized by him and others. In 1934, Miller and

Abbott¹⁰ overcame this, and they with Johnston¹¹ and others¹²⁻¹⁴ have given a new impetus to the conservative treatment of these cases by combining the principle of Monks with that of Wangensteen. They have shown conclusively that a long, flexible rubber tube of special design placed in the stomach will pass through the pylorus and work its way down to the obstructing point, emptying the bowel of gas and liquid contents, the collapsed bowel threading itself on the tube as Monks had done at operation.

It is not surprising that many of us in this hospital should view with some alarm these recent enthusiastic reports in favor of a conservative form of treatment, fearing lest much be lost which has been gained by the teaching of early diagnosis and early operation. Therefore, before adopting a method so different in concept from the present teachings, it has seemed imperative to bring the earlier work of Scudder, Richardson and McIver up to date, and to study our more recent cases in an especial endeavor to evaluate, if possible, the results of their teaching, and to clarify more completely in our own minds the indications for early operation as against delayed or nonoperative treatment.

In this review we have not followed exactly the course of our predecessors. We have restricted our cases to definite acute mechanical obstruction of the small bowel occurring in patients with or without previous operation, exclusive of obstruction secondary to external hernia. We have not included obstruction of a plastic nature arising in the course of such a condition as peritonitis, as there is no question but that this type of obstruction is ideally treated by suction, nor have we included cases secondary to obvious carcinoma, or occurring as complications of chronic disease where the obstruction is of secondary importance. There are available for study 136 cases treated during the last fifteen years.

In addition to ascertaining the comparative re-

*From the medical services of the Massachusetts General Hospital, Boston. Presented at the annual meeting of the New England Surgical Society, Boston, Massachusetts, September 29, 1939.

†Visiting Surgeon, Massachusetts General Hospital; Instructor in Surgery Harvard Medical School.

‡Resident Surgeon, West Surgical Service, Massachusetts General Hospital.

sults during the last four decades, it was hoped that this study might suggest answers to the following questions: What are the factors from which an early and accurate diagnosis can be made? How important and how frequent is strangulation of the blood supply to the obstructed loop? Can one with reasonable assurance distinguish between simple and early obstruction with strangulation? Is there any distinct time after the development of obstruction when one can safely say that strangulation obstruction will not occur? What factors other than strangulation contribute to the high mortality? Are there any criteria by which one may say that immediate operation is indicated, or that conservative treatment, either as a preliminary or an active form of management, should be undertaken?

DIAGNOSIS

History

Seventy per cent of all the patients in this series had had some previous laparotomy, and if one excludes the infants with intussusception, 80 per cent of all our patients had had a previous abdominal operation. The length of time between the operation and the development of obstruction is of no significance, in 1 case having been thirty-four years. Six per cent of our patients had been operated on for a previous obstruction, and 20 per cent had had symptoms suggestive of previous attacks with spontaneous recovery.

Symptoms

The commonest presenting symptom was pain, being the chief complaint in 98 per cent of our cases. It was usually sudden in onset (80 per cent) and colicky. Though one might well expect small-bowel pain to be at or above the umbilicus, it was described as upper abdominal in 35 per cent of the cases, lower abdominal in 35 per cent, generalized in 20 per cent and in various locations in 10 per cent. The characteristic cramplike pain may, as the obstruction progresses, become steady, and in a few cases it entirely disappeared.

Vomiting was present to some degree in 93 per cent of the cases. In many, however, it was not a prominent symptom, the so-called fecal vomiting that one is accustomed to associate with small-bowel obstruction was a late symptom.

Characteristically there was cessation of either movement of the bowel or passage of gas by rectum following the onset of pain. In 60 per cent of our cases there was nothing passed by rectum after the early symptoms of the obstruction. However, in the remainder of the cases small amounts of gas or feces were frequently passed, particular-

ly after enemas, and in a few the bowels moved well shortly after the onset of the obstruction.

Symptoms may arise at any time in the day or night. Not a few of our patients were awakened from a sound sleep by the onset of their obstructive pain.

Physical Examination

In the early stages of obstruction there is little effect on the general condition of the patient.

As has been pointed out by Donaldson,¹⁵ Morton,¹⁶ Herrin and Meek¹⁷ and others, distention comes late in the course of the disease and should not be awaited for a diagnosis. There was no discernible distention in 40 per cent of our cases.

Tenderness is not a prominent symptom, although in most cases it is present in some degree, particularly in relation to the point of obstruction. In late cases, especially those of strangulation obstruction, tenderness and spasm are usually found. This will be discussed more in detail in the section on the differential diagnosis of simple and strangulation obstruction.

Obstructive peristalsis, elicited with the stethoscope and characterized by periodic high pitched tinkles, often though not always synchronous with colicky pain, was found in 73 per cent of our group. It must be remembered, however, that in the later stages of obstruction the abdomen may frequently be relatively silent, and long periods may elapse between peristaltic noises, which in many cases may be quite faint. Twelve per cent of our patients were described as having normal peristalsis, and it was stated to be absent in 15 per cent.

Laboratory Findings

The temperature is usually normal even after the obstruction has been present for some time, unless strangulation obstruction and resulting peritonitis are present. The pulse in the earlier stages of the disease is normal or only slightly elevated. Even in the early stages there may be no change in the character or rate of the pulse. A rapid pulse in a patient with intestinal obstruction is indicative of a serious complication.

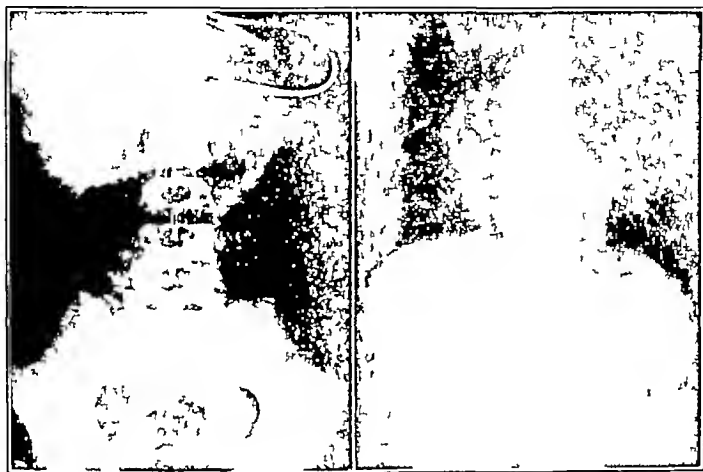

The white-blood-cell count is variable. While most commonly 15,000 or below, it varied from 3000 to 38,000 in our cases. The value of the white-cell count as a differential diagnostic sign of simple and strangulation obstruction will be discussed later.

As regards blood constituents, variations from the normal depend on the duration of obstruction, with consequent dehydration and chloride loss. In early obstruction, alterations are not expected and

are not found, but in late stages the nonprotein nitrogen rises and the chlorides fall. This rise of nonprotein nitrogen caused a mistaken diagnosis in a fatal case in this series, the patient having been judged to be in renal uremia.

The so-called scout x ray film of the abdomen is the most important single objective finding in the patient with small-bowel obstruction. Its significance was first stressed in this country by Case¹⁸ in 1915, but its use did not become prevalent

been emptied of gas and fluid and without the giving of an enema, because of the gas which may be injected into the large bowel and thus confuse the picture. It is not within the province of this paper to go into the details of the x ray findings.¹⁹⁻²³ Suffice it to say that distended coils of small bowel were demonstrated in one of our cases three hours after the onset of symptoms. On the other hand, the characteristic step ladder arrangement (Fig. 2) is found only in the

A

B

FIGURE 1

Scout films in lying (A) and sitting (B) positions showing gas shadows and fluid levels in distended coils of small bowel

until the present decade. Its value as a diagnostic sign cannot be overemphasized, particularly if the surgeon or radiologist has had experience in the interpretation of the plates. Two views are generally taken, the first with the patient supine, and the second in the sitting position. The former position (Fig. 1A) is superior for the study of the gas patterns of the bowel, the latter (Fig. 1B) is better for the determination of fluid levels. It is probably not saying too much to state that a close study of such films in association with a carefully taken clinical history should result in an accurate diagnosis in a very high percentage of cases. In 92 per cent of the cases in this series in which x ray films were taken there was fairly positive evidence of obstruction. In the remaining cases the evidence was suggestive. It is our experience that x ray films should be taken after the stomach has

later stages. Diagnosis should be made, given the opportunity, long before this occurs, just as it should be made before the development of fluid levels. It should be stated, however, that there are times when the x ray picture is most confusing. Small amounts of air may be found scattered through the bowel below an obstruction. In early cases a second film taken after an interval of six or eight hours may be of great help when there is doubt as to the diagnosis or as to the progress of the condition. There are other times when the shadows are such as to be difficult of interpretation. We have seen the small bowel so dilated as to be interpreted as a markedly distended cecum (Fig. 3A). In certain conditions of this type the giving of a small amount of barium by rectum may entirely clarify the picture with little or no risk to the patient (Fig. 3B).

We cannot agree with Wangensteen⁹ that dilatation of the small bowel is rarely seen in cases of

FIGURE 2 *Characteristic Step-Ladder Arrangement in Late Small-Bowel Obstruction*

obstruction of the large bowel. We have repeatedly seen it in such cases, even when the lesion was as low as the sigmoid (Fig. 4)

chanical obstruction of the small bowel are these: a history of sudden and usually severe abdominal pain, colicky in nature, particularly in a patient with previous laparotomy, vomiting, usually following the pain, which may be small in amount or in the later stages copious and fecal, evidence of one or more distended loops of small bowel, as shown by a scout x-ray film of the abdomen, and active, high-pitched, tinkling peristalsis, audible over the abdomen.

Simple Versus Strangulation Obstruction

The importance of the recognition of early strangulation obstruction cannot be overemphasized. Wangensteen^{8, 9} believes that the experienced observer can accurately distinguish between obstruction which is simple in character and that with early interference with the blood supply to the obstructed loop. He places strong emphasis on the presence or development and extension of abdominal tenderness and spasm in a case where the findings are those of acute obstruction. The suggestion of a mass felt through the abdominal wall or on pelvic or rectal examination is in his judgment confirmatory evidence of a strangulation obstruction. Recognizing our own inability in the past to make this differential diagnosis, we have carefully studied these cases with this in mind.

Pain in strangulation obstruction may be more

A

B

FIGURE 3

In A, the large gas shadow in the right abdomen was interpreted as cecum. In B, taken after a barium enema, the unrotated cecum is seen on the left. The distended coil on the right is small bowel.

In summary, then, we may say that the five important early diagnostic criteria in acute me-

abrupt in onset and more severe, and is more apt to be quite steady with exacerbations or to change

from colicky to steady with the onset of strangulation. In fact, in 5 of our cases the onset was so sudden and the associated tenderness and spasm so marked that a diagnosis of perforated viscus was made.

Gangrene may develop very quickly. The nature of the obstruction may be such as to strangle the supply to the obstructed loop in the early minutes of the process. One of our patients who entered the hospital three hours after the onset of pain, and who was promptly operated on after the usual emergency ward routine of diagnosis and preparation, showed at operation a gangrenous

FIGURE 4. Distended Loops of Small Bowel Secondary to Obstruction of the Sigmoid from Carcinoma.

segment of bowel that required resection. Moreover, the transition from simple to acute strangulation obstruction may occur with little or no warning in a patient under observation, and this transition may happen as well between 7 p.m. and 7 a.m. as during the hours of more careful observation. It has been suggested that if forty-eight to seventy-two hours have passed with no sign of strangulation having been elicited, the chances are that there is or will be no strangulation. Half of our patients with strangulation obstruction requiring resection were operated on following a delay of six hours up to several days after an admission history of obstruction of three or more days' duration. This we feel justified in interpreting as evidence that a diagnosis of strangulation

obstruction could not have been, and from the record was not, made at the time of admission, and yet resection of a strangulated loop of bowel was later necessary. We may assume, therefore, that the interval that has elapsed between the onset of symptoms and the arrival of the patient at the hospital, even though it exceeds seventy-two hours, cannot be safely taken as evidence against the subsequent development of a strangulation requiring resection.

It has been our impression that an elevation of the white-cell count above 18,000 is strongly suggestive of an interference with the blood supply to the segment of obstructed bowel. A study of the counts in these cases, however, does not confirm this. Although 35 per cent of the patients with suspected strangulation obstruction had white-cell counts of 20,000 or more, 32 per cent of this subgroup showed no evidence of strangulation at operation and interestingly enough, the highest count in the series, 38,000, occurred in a case of simple obstruction. Even though 50 per cent of the patients with simple obstruction had white-cell counts of 15,000 or less, so many of the cases requiring resection had counts between 3000 and 15,000 that relatively little help may be expected from the leukocytic count. In spite of what has been said, we believe that a rising white-cell count should be interpreted as suggesting strangulation of the obstructed loop.

As previously suggested, a rapid pulse suggests a serious complication in a patient with intestinal obstruction. With but few exceptions, patients requiring resection had a preoperative pulse of 100 or above. On the other hand it is of even greater significance that in the early stages of strangulation, before its toxic effects are manifest, the pulse will not be altered, and therefore the evidence of elevated pulse can be taken as evidence only of late strangulation and is of no diagnostic value in differentiation in the earlier stages.

Tenderness, as pointed out by Wangenstein⁸ is of the greatest significance. On the other hand, as he also points out, there will be localized tenderness over the point of obstruction if this is at such a place that the examining fingers can exert direct pressure over it. Therefore, except in the hands of the most experienced surgeons we do not believe that this is a safe criterion to follow, unless one assumes that any tenderness in a patient with a diagnosis of intestinal obstruction, be it localized or spreading, is to be taken as evidence of strangulation and immediate operation advised. We can therefore only conclude from our own experience and from a thorough review of these records that we ourselves are not able, and those surgeons at the Massachusetts General Hospital under

whose care these patients have been were not able, with any high degree of accuracy, to differentiate the early stages of strangulation and simple intestinal obstruction

Mechanism of Obstruction

It has been our impression that acute small-bowel obstruction of the type under discussion usually occurred at a single point and was most frequently caused by a band arising from previous operation or by a point of adhesion, secondary either to trauma at previous operation or to some pre-existing disease (Table 1) Under single-point ob-

TABLE 1 Mechanism of Obstruction

| CAUSE OF OBSTRUCTION | CASES WITH PREVIOUS OPERATION | CASES WITHOUT PREVIOUS OPERATION | TOTAL |
|----------------------|-------------------------------|----------------------------------|-------|
| Band | 48 | 7 | 55 |
| Adhesions | 17 | 5 | 22 |
| Intussusception | 1 | 17 | 18 |

| Not stated | 16 | 4 | 20 |
| Totals | 94 | 42 | 136 |

struction we include that secondary to a Meckel's diverticulum, to intussusception or to a foreign body within the lumen of bowel A review of these cases seems to substantiate this belief, since 81 per cent of the total number of cases had some single point, the release of which was adequate to relieve the obstructing mechanism This is of no little importance in considering the management of these cases A single-point obstruction more completely predisposes the development of gangrene of a segment of bowel than is the case where the obstruction is more adhesive and where longer segments of the bowel are involved Moreover, the release of such an obstruction is an extremely simple surgical procedure, and if it is done under conditions which are reasonably favorable and at a time before complications have developed, can be accomplished at very small risk to the patient

RESULTS

One hundred and thirty-six cases fulfilled the selection basis outlined above Eight patients were never operated on because of early recovery, either spontaneously or under conservative treatment There was no x-ray diagnosis to be found in the records of these cases, but the clinical evidence of obstruction was strong

Twenty-seven of the 136 patients died, a hospital mortality of 20 per cent Four of these deaths were in patients not operated on One occurred soon after admission, the patient, already in rather

poor condition, vomited a tremendous amount of foul gastric residue, and during passage of a stomach tube aspirated some of the fluid and died. The other 3 deaths that occurred without operation were from strangulation obstruction because the diagnosis was made too late or not at all. Twenty-three (18 per cent) of the 124 patients operated on had a fatal termination The vital facts relative to the fatal cases are given in Table 2 We shall now attempt to analyze the contributing factors

Age

The average age of our patients was thirty-three. The average age of those who recovered following operation, however, was twenty-eight, whereas that for the fatal cases was fifty-three It is strongly suggested that obstruction in the aged should be managed differently from that in the young or middle-aged, and if one studies Table 3 one can-

TABLE 3 Relation Between Age and Mortality

| AGE | NO OF CASES | NO OF DEATHS | MORTALITY RATE % |
|-----------------------|-------------|--------------|------------------|
| All patients | 136 | 27 | 20 |
| Under 60 years | 114 | 13 | 11 |
| Sixty years or over | 22 | 14 | 64 |
| Seventy years or over | 8 | 6 | 75 |

not but be impressed with the fact that 14 (64 per cent) of the 22 patients sixty years of age or over died, whereas only 13 (11 per cent) of the 114 patients under sixty did so While the number of cases is too small to be conclusive, it seems significant that 75 per cent of the 8 patients seventy years of age or over died following operation There were, of course, other factors, but when one faces a mortality of 64 per cent in any given group, one should seriously consider some change in the form of therapy used

Previous Operation

McIver,³ among others, has remarked that the mortality of patients with mechanical obstruction who have not been previously operated on is sig-

Autopsy

per cent in those with a previous laparotomy (Table 4)

The nature of the obstruction in these patients (Table 1) may well not be the significant factor in this increased mortality. A study of these cases (Table 4) shows that in the fatal cases not previously operated on the patients were on the average twenty-one years older than those with previous operation, furthermore, treatment had been delayed on an average of two days more after hospitalization, and the duration of obstruction had been almost twice as great. This delay in diagnosis is probably partly due to the fact that surgeons have been trained to consider that any attack of abdominal pain in the presence of an abdominal scar means acute small-bowel obstruction until proved otherwise, we therefore undoubtedly think in terms of obstruction in the patient with a previous operation, whereas the absence of any etiologic factor in the patient without previous operation renders less likely the careful consideration of acute small-bowel obstruction as the cause of symptoms. This is particularly so in the older group of patients.

Duration of Obstruction

There has been uniform agreement that the duration of obstruction plays a leading role in the mortality,^{16, 24-27} and this was shown even more strikingly than we had expected in the group of patients under discussion here. Forty-three patients were operated on within twenty-four hours of the onset of obstruction, and in this group there were no deaths. There would then seem to be no question but that any patient in whose case a diagnosis of small-bowel obstruction is made or even strongly suspected within the first twenty-four hours after onset can be operated on with great safety, and can and should be operated on immediately.

It may be of significance, however, that after twenty-four hours the additional delay does not seem to carry with it a much higher mortality. This important element of time affects other factors, such as the type of operation required, and will therefore be discussed further.

Type of Operation

It is undoubtedly not so much the magnitude of the operation that is responsible for the higher mortality where more extensive operations are required, as the advanced stage of the disease and the associated complications, such as peritonitis, known to accompany it. It is therefore interesting to note that those cases operated on sufficiently early, or under conditions permitting the simple lysis of a band or adhesive point,

showed an extremely low mortality (3 per cent). On the other hand, those cases in which strangulation obstruction had occurred, requiring resection of a segment of bowel, had the highest mortality (52 per cent). Again, one sees that important factor, time, and the prominent part it plays in the type of operation in cases of acute small-bowel obstruction.

TABLE 5 Effect of Duration of Symptoms on the Type of Operation

| INTERVAL BETWEEN ONSET AND OPERATION | TYPE OF OPERATION | | |
|--------------------------------------|--------------------|-------------------------------------|-----------|
| | LYSIS OF ADHESIONS | ILEOSTOMY OR SIDETRACKING OPERATION | RESECTION |
| | % | % | % |
| Twenty four hours or less | 93 | 5 | 2 |
| Twenty five to 48 hours, inclusive | 64 | 8 | 28 |
| More than 48 hours | 33 | 41 | 23 |

A patient operated on within the first twenty-four hours after onset of obstruction has nine chances out of ten of requiring a simple lysis of a point of adhesion (Table 5). In the second twenty-four hours his chances are only six out of ten that a simple operation will suffice, and after forty-eight hours have elapsed they are only three out of ten.

Hospital Delay

One should probably distinguish between the delay due to the patient's late arrival and that due to the inability of the surgeon to make the diagnosis, or deliberately accepted in the management of the patient. We have gone over these cases with this in mind, and have considered a delayed operation as one which was postponed six or more hours after admission (Table 6). This

TABLE 6 Effect of Hospital Delay on Mortality

| INTERVAL BETWEEN ONSET OF OBSTRUCTION AND ADMISSION | NO DELAY | | | DELAY (6 HOURS OR MORE) | | |
|---|-------------|--------------|-------------|-------------------------|--------------|-------------|
| | NO OF CASES | NO OF DEATHS | MORTALITY % | NO OF CASES* | NO OF DEATHS | MORTALITY % |
| | | | | | | |
| Twenty four hours or less | 42 | 0 | — | 17 | 5 | 29 |
| Twenty five to 48 hours inclusive | 12 | 3 | 25 | 12 | 3 | 25 |
| More than 48 hours | 18 | 6 | 33 | 23 | 6 | 26 |
| Totals | 72 | 9 | | 52 | 14 | |
| Averages | | | 12 | | | 27 |

*We have omitted 3 fatal cases of strangulation obstruction in which the patients were not operated on because when diagnosis was made after a delay it was too late. We have also omitted 8 patients who recovered without operation. This is to facilitate the comparison of operative statistics in cases of delay and no delay as it happens this does not affect the mortality statistics.

delay has occurred either because of failure to make the diagnosis, or because the surgeon in charge was under the impression that the patient was improving either spontaneously or with suction, and that operation was therefore unnecessary. As a

matter of fact, almost without exception any case in which there was a delay of six hours or more had elapsed. The average hospital delay in this series was two days.

A study of these cases would seem to be essential to the formulation of proper management in the future. Forty-two patients admitted to the hospital within twenty-four hours of onset of symptoms were operated on immediately, with no deaths, whereas 5 (29 per cent) of 17 patients who entered the hospital within twenty-four hours of the onset of symptoms, but for one reason or another were not operated on as emergencies, died. However, one sees in the second twenty-four hours a mortality that is about the same with or without delay, whereas after forty-eight hours had elapsed the gross mortality of the 23 patients where operation was delayed was smaller than that in the 18 cases where immediate operation was done. It would therefore seem justifiable to conclude, regardless of other factors, that immediate operation should be done when one sees a patient less than twenty-four hours after the onset of symptoms, that early operation may be done in the second twenty-four hours, but that after forty-eight hours have elapsed immediate operation should not be undertaken.

Strangulation

There seems to be no question in anyone's mind that the most serious complication in the type of obstruction under discussion is the strangulation of the circulation to the loop of obstructed bowel. There is, however, a slight difference of opinion as to the accuracy with which early diagnosis can be made in this complication, as to how frequently it occurs and as to what part it plays in the total mortality in cases of obstruction.

We have already considered the differential diagnosis between simple and strangulation obstruction, and are forced to admit that in our hands a differential diagnosis can be made with reasonable accuracy only in the later cases. Strangulation obstruction occurred in 33 per cent of all our cases. A comparison with the cases of the previous decade, as reviewed by McIver,³ shows that this is a distinct drop from the figure of 50 per cent in a comparable group of cases. That it is the most important factor in the fatal outcome is evidenced in our own cases by the fact that 16 of the 27 deaths were referable to gangrene. Thus 59 per cent of the fatalities were the result of interference with the blood supply to the involved loop. This is comparable to Wangenstein's⁴ series (excluding hernia), where 60 per cent of the

deaths classified as related to obstruction were due to gangrene.

Comparison of the Results by Decades

We believe it to be of no little importance to compare the results reported from this hospital in the three preceding decades with those in the last ten years (Fig 5*). We see a striking drop

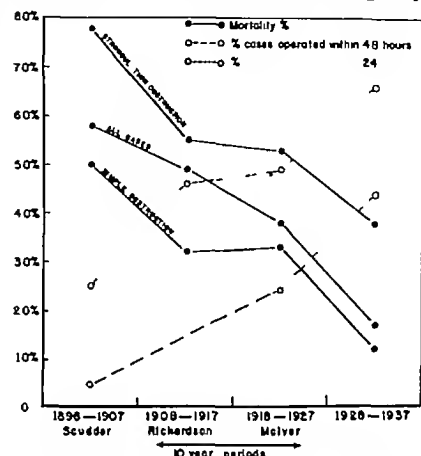

FIGURE 5

The graph shows clearly the progressive decrease in mortality over a forty-year period. The greatest drop has been in the last decade. This decrease has come simultaneously with the increase in the proportion of cases operated on within forty-eight and particularly twenty-four hours of the onset of symptoms.

in mortality in the cases of both simple and strangulation obstruction. Many factors contribute to this marked and progressive improvement. However, it would seem justifiable to suggest the following:

The results of improved surgical treatment are reflected more in the cases of simple than in those of strangulation obstruction.

The increase (20 per cent in the last decade) in the number of patients operated on within twenty-four hours after the onset of symptoms is reflected in the lower mortality among the cases with strangulation obstruction.

The most productive group for further improvement is that with strangulation obstruction and inasmuch as most of these patients die of peritonitis secondary to the pathologic process rather than to any technical surgical error, earlier diagnosis and operation before gangrene and peritonitis have ensued would seem indicated.

*Figure 5 reports the mortality of ten-year period immediately after McIver's report. All other statistics and tables refer to fifteen-year period (July 1, 1924 to July 1, 1939).

Any method of treatment that tends to delay operation in patients entering the hospital within twenty-four hours of the onset of symptoms may be followed by an increase rather than a decrease in mortality

CONCLUSIONS

In beginning this study it was our hope that certain vital questions in relation to the diagnosis and management of this group of cases might be clarified. We feel warranted at this time in answering these questions as follows

In addition to a careful history-taking and physical examination, the routine use of the scout film of the abdomen should make possible a definite diagnosis of early acute obstruction of the small bowel in a high percentage of cases

Strangulation is the most important single factor in determining the outcome of a case of acute small-bowel obstruction. It was present in 33 per cent of the total group, and was the cause of death in more than half the fatal cases

Regardless of Wangensteen's conviction that a differential diagnosis can be made of early strangulation and simple obstruction, we are forced to conclude that we ourselves were unable to make this differential diagnosis in early cases, and that certainly it was not made early enough to prevent resection in a substantial proportion of the cases reviewed by us

There is no definite period beyond which one can say that strangulation obstruction will not occur. One can say that it may occur within four hours of the onset of symptoms, that operation done within the first twenty-four hours is almost certain of success regardless of the presence or absence of strangulation, and that after forty-eight hours have elapsed while the danger still exists, the advantages of delay probably outweigh the risk of strangulation

Certain factors other than strangulation contribute to the high mortality. Though these are varied, the strongest ones are age and the duration of the obstruction. In addition the presence of distention of the small bowel at operation presents a mechanical difficulty which has been a factor in 30 per cent of the deaths in this series. One can therefore add to the triad of gangrene, age and duration, suggested by McIver,³ the mechanical factor of distention

The one positive essential for operation is that the patient present himself for treatment within the first twenty-four hours after the onset of symptoms. It seems doubtful from a review of these cases that any complication relative to the obstruction itself would justify delay of more than a

few hours in the preparation of such a patient for operation. Almost certainly any such factors—shock, rapid pulse, tenderness and distention—would be the result of strangulation obstruction, and immediate operation at the earliest possible time would be imperative. After twenty-four hours have elapsed, other factors such as distention, dehydration and chemical imbalance rapidly assume importance equal to or surpassing the risk of strangulation. Therefore, in cases where the obstruction is of twenty-four hours' duration or longer, delayed treatment would seem indicated in any patient sixty years of age or older unless there is definite evidence of strangulation obstruction

RECOMMENDATIONS FOR TREATMENT

There is probably no condition in which the results to be obtained depend so much on experience, judgment and individual treatment as that in cases of acute mechanical obstruction of the small bowel. However, in view of the above findings, and judging from the experiences of Wangensteen,⁸⁻⁹ Miller, Abbott and Johnston¹⁰⁻¹⁴ and others, as well as from our own, we feel justified in suggesting the following principles for the management of such cases

The degree of dehydration and chemical imbalance should be evaluated and appropriate methods instituted for relief, with observance of the necessity of transfusions for certain patients with strangulation obstruction.²⁸⁻²⁹

A double-lumen Miller-Abbott or similar tube should be passed immediately, to be left down whether or not operation is undertaken

Immediate operation is indicated in any case examined within twenty-four hours after the onset of symptoms. We see no place for conservative treatment in this group

Early operation should be done on a patient seen in the second twenty-four hours after onset

Delayed or nonoperative treatment is indicated in the absence of definite signs of strangulation obstruction in any patient seen later than forty-eight hours after the onset of symptoms, or in any patient over sixty years of age, unless the obstruction is of less than twenty-four hours' duration and the patient is in good condition, without distention

If conservative treatment is instituted, the following routine should be followed: serial abdominal films at twelve-hour to twenty-four hour intervals, in order to follow the progress of the tube and the degree of distention, bi-daily white-cell counts*, and frequent abdominal ex-

*Even though normal or low white cell counts do not exclude strangulation, we think that a rising count should be accepted as evidence of increasing interference with the blood supply of the involved segment of bowel.

amination, at least every four or six hours, with the examiner particularly alert for the development of point or rebound tenderness.

If decompression cannot be accomplished by intubation, and laparotomy under general or spinal anesthesia seems too hazardous, the distended bowel should be drained by inserting a catheter in a distended loop under novocain anesthesia. No attempt at exploration should be made at this time.

If decompression is successfully accomplished and normal bowel action re-established, it is our belief that for a good risk patient an operation of election at the same hospital admission should be given serious consideration. We believe that since the obstructing mechanism is probably still present, and since 26 per cent of our patients have given a history of previous attacks, the risk of lysis of the point of obstruction is less than that of future obstruction, unless the patient is assured of competent surgical care within the first twenty-four hours of any subsequent attack.

DISCUSSION

DR. RICHARD THOMPSON, Boston. I brought with me one of the Miller Abbott tubes and will speak briefly of how we use it. It has a very thin balloon at the end. The up beyond this balloon is metal and perforated, and is connected with one of the lumens that run throughout the whole ten feet. The other lumen goes to the inside of the balloon. The balloon can be inflated and held inflated by the clamping off of the other limb at the proximal end. We lubricate the balloon with surgical lubricant because oil or grease will injure the rubber and pass it through the nose to get it into the stomach. The technique of getting it beyond the pylorus is sometimes quite troublesome, and we have had some experiences which have helped us to learn how it may be worked through.

Of course x-ray examination by using the fluoroscope or a flat plate if the patient is too ill to be moved to the x-ray department, is of great value. If one is in extreme haste to get the tube down fluoroscopy is very important; however, if for any reason one wishes to use the tube for purely diagnostic purposes or does not feel anxious to get it down immediately because the obstruction is subacute the patient may simply lie in bed in any position, not necessarily on the right side, and take cold preferably ice cold fluids by mouth. If the tube is given a little urging through the nose, it will usually pass the pylorus.

Of course, as Dr. McKittick said, the ideal place for the use of this tube is in early postoperative obstruction when the condition is due to plastic exudate about the bowel and when one feels perfectly sure that there is no constricting band that may cause gangrene of a loop. After the tube has been passed in such cases, recovery is made easier because we can give fluids, and even milk and soft solids, at a much earlier time than we should dare to without the safety valve effect of the tube in the small bowel.

Certain patients who obviously have something wrong in the small intestine, perhaps regional enteritis, can be very effectively diagnosed with the Miller Abbott tube.

DR. S. PETER SARRIS, Boston. There is one aspect of the treatment of acute mechanical obstruction of the small bowel that Dr. McKittick did not mention that is the use of 95 per cent oxygen in relieving distention. This method, which was introduced by Dr. Jacob Fine, of Boston, is based on sound physiological principles. The first is the observation by Meier that the chief component of gas in the distended small bowel is nitrogen. The second principle is that gases diffuse through a semipermeable

membrane in proportion to their partial pressure. Dr. Fine therefore administered 95 per cent oxygen, which washes the nitrogen first out of the lungs and then out of the blood stream. Finally there begins a diffusion of nitrogen from the intestines into the blood stream. As a result, distention is diminished within twenty-four hours in about 60 per cent of such cases.

We have not used this method extensively, but have seen encouraging results from it. We suggest that its outstanding value lies in supplementing the treatments outlined by Dr. McKittrick. Whether one is going to operate or to use the Miller Abbott tube, no harm will come from putting the patient in a 95 per cent oxygen tent, if he is badly distended.

I wish to say a word about the difficulties we have had with the Miller Abbott tube. We do not profess to be experts, but there is one thing that we have learned, and which the originators of the tube themselves admit. That is that in about 15 per cent of cases it is impossible to get it through the pylorus. Another thing we have discovered is that these tubes need extremely careful attention if they are to function properly.

A complication in small bowel obstruction is knotting of the tube. This is probably extremely rare, but it certainly occurred in one case. The tube was passed, but shortly thereafter drainage ceased. Accordingly the tube was pulled out, and as the end of it reached the pharynx the patient choked and almost died of asphyxia. Quick thinking on the part of the assistant who was drawing out the tube led him to puncture the balloon, and so allow the tube to be extricated. Apparently the tube had become knotted, and this prevented not only aspiration of the small bowel contents but also deflation of the balloon.

DR IRVING J. WALKER, Boston. I should like to mention two rather interesting experiences with the Miller Abbott tube. The first was a knotting of the tube in the stomach. After the tube was passed the patient was x-rayed to determine its position. One film showed what was apparently a knotting. This did not worry us much, the tube was withdrawn into the mouth, the knot was untied and the tube was passed into the stomach again.

The second incident was rather distressing. As you know, the Miller-Abbott tube is a two-way affair, one tube leading to the balloon, and the other projecting through and beyond the balloon. The connecting tips of the metal yoke do not indicate to which tube each leads. It seems to me that the manufacturer could indicate the tip leading to the tube that is to be used for inflating the bal-

loon, and thus aid in avoiding embarrassing situations like the one that occurred in the following case. The patient was thought to have small bowel obstruction, due to bands following a previous appendectomy. A flat plate of the abdomen showed no fluid levels. We decided to pass the tube, and did so. Eighteen hours later the balloon was well down and the small bowel was decompressed. We later operated and found an obstructive band in the ileum which we divided. The tube was left in place for further decompression. After this had been accomplished, we resolved to feed the patient through the tube projecting beyond the balloon. Apparently the nurse tried to use the tube leading to the balloon. She soon realized that the food was not entering the bowel, and therefore shifted to the other tube. The feeding was carried out for two days, at the end of which time it was decided to remove the tube. This I undertook to do. The tube seemed to come out rather harder than usual. However, I gradually worked it up farther and farther. I then became suspicious that the balloon was not deflated and was in the stomach. I then tried to pass fluids through the tube leading to the balloon, but was unsuccessful. Another attempt at withdrawal was made, but again resistance was encountered at the cardiac end of the stomach. After considerable pulling the balloon exploded within the stomach and the tube was easily withdrawn. Later it was discovered that the tube leading to the balloon had become plugged with the feeding material. The incident worried me considerably, especially at the time traction was being placed on the balloon when it had reached the cardiac end of the stomach, because of the possibility of rupturing the lower end of the esophagus.

We have found the Miller-Abbott tube of special value in the differential diagnosis of paralytic ileus and mechanical obstruction. I refer to those patients who four or five days after operation show distention, and more particularly to cases in which there is infection within the peritoneal cavity. Such cases often offer a problem as to whether one is dealing with a peritoneal exudate that has resulted in a kinking of the bowel, paralytic ileus or a combination of both. We have found that the tube decompresses the small bowel regardless of whether the condition is paralytic ileus or mechanical obstruction. When the bowel has been decompressed, we have passed 5 or 10 cc of a weak barium solution through the tube that projects beyond the balloon. This at once answers the question whether one is dealing with paralytic ileus or mechanical obstruction. In the former, the barium is found by x-ray to be in the large bowel. In the latter it will not have passed beyond the ileocecal valve.

THE PREVENTION OF DIABETES MELLITUS

A Clinical Lecture

REGINALD FITZ, M.D.*

BOSTON

FOR several years, as an annual event in his course on preventive medicine at the Boston University School of Medicine, my friend Dr David L. Belding has asked me to give a lecture on the prevention of diabetes mellitus. This year I propose to thank Dr Belding for the compliment by retreating in print for in order to give the kind of lecture which he would like, vastly more knowledge is needed than is at present available and therefore I am asking my New England colleagues for assistance.

When all is said and done, peculiarly little is known of the cause of diabetes. Certainly to find an assured organic basis for the disorder is by no means easy, in spite of the excellent histological observations on the islands of Langerhans made by Opie¹ and by Weichselbaum and Staog² in 1900 and 1901, and in spite of the demonstration of the hydropic degeneration of the "beta" cells of these islands in experimental diabetes which Allen³ and Homans,⁴ working independently were able to accomplish a few years later.

Until recently, the physiological basis for believing that the pancreas has a good deal to do with diabetes seemed clearer, for in 1889, as everyone remembers, Minkowski,⁵ with the aid of von Mering, showed that ablation of the pancreas in animals induces a true diabetes mellitus, with glycosuria and hyperglycemia. This discovery, in fact eventually led Banting and Best⁶ to find insulin, an extract from the islet cells of the pancreas that has made of diabetes an easily treatable condition.

The work of recent investigators like Houssay⁷ and Young⁸ now throws a reasonable doubt on the belief that the pancreas primarily needs to be at fault in diabetes. Last winter at the Harvard Medical School, as many medical students recall, Dr Young showed slides from a diabetic animal which had developed a fatal diabetes although the pancreas had been left untouched. The disease was induced by injections of extract from the anterior lobe of the pituitary gland, and the resultant changes that took place in the pancreas secondary to such treatment were indeed remarkable.

Thus in diabetes we have a disease, with an

underlying cause still to be identified, that produces a clear-cut, unmistakable clinical picture. Diabetes clinically, however, is such a respectable, well studied affair that of course much is known of its natural life history, and hints have been given as to its preventability. In the sixth edition of Joslin's⁹ book on the treatment of diabetes mellitus, there is an interesting chapter dealing with this phase of the disease.

Joslin comes out flat footed; he says that heredity is the basis of diabetes. In the same volume White and Pincus elaborate on his views. They say that the evidence that the potentiality of developing diabetes is inherited rests primarily on four factors: the almost simultaneous occurrence of diabetes in both members of pairs of similar twins; its greater incidence in the blood relatives of diabetic patients than in those of a control population; the demonstration that Mendelian ratios of the recessive type are found in a large series of cases selected at random; and the demonstration of expected ratios of a diabetic tendency in presumably latent cases.

Their figures on twins are striking. In 19 pairs of dissimilar twins, one of whom became diabetic, the incidence of diabetes in both twins was 10 per cent. In 16 pairs of similar twins, one of whom became diabetic, it was 69 per cent. These figures are all the more remarkable because in the dissimilar twin group 10 per cent of the parents were diabetic, compared with only 6 per cent of the parents in the similar twin group.

The incidence of diabetes in the parents and siblings of diabetic patients differs significantly from that in the parents and siblings of non-diabetic subjects. White and Pincus found that among 434 parents and siblings of diabetic patients, 67 per cent were afflicted with the disease, whereas among 1219 parents and siblings of a group of patients without diabetes, only 1.2 per cent had it. These figures also seem convincing.

White and Pincus are as conservative as possible. They say that although the excess of diabetes in the blood relatives of diabetic patients suggests inheritance, it does not prove it, for to do so a pattern must be demonstrable. They have drawn some interesting speculation from Joslin's material, to the effect that diabetes does, in fact, follow a definite pattern of inheritance.

*Lecturer on the history of medicine, Harvard Medical School, Boston.

and that this pattern, according to the Mendelian hypothesis, is one of simple recessiveness. On the other hand, Perkins¹⁰ regards the inherited tendency to develop diabetes as a dominant characteristic.

Admitting all this to be true,—that the cause of diabetes is uncertain, that heredity is the basis of it and that laws of heredity govern the transmission of the disease according to the Mendelian theory and follow the pattern of simple recessiveness or of dominance,—we are not much farther ahead when we begin to speak of prevention. For we do not know what determines the onset of diabetes.

Some secondary factor seems needed to activate the diabetic gene. White and Pincus chose the anterior pituitary lobe. They believe that something happens to this mysterious little gland which makes it hyperactive. Given an individual who inherits diabetic susceptibility and let his anterior pituitary lobe for some unknown reason become overactive, and he will develop what we clinicians call diabetes.

Joslin, on the other hand, blames obesity for being the flint that when properly struck makes the spark that fires the gene that causes diabetes. And he has a great deal with which to support this theory—statistics on the frequent association between diabetes and obesity, statistics from insurance records showing that the subsequent development among persons accepted for insurance after medical examination and known not to be diabetic is far more frequent among overweights than among persons of average weight or less, statistics regarding conjugal diabetes where, in his experience, both husband and wife have been fat, the implication being that they contracted the disease from exposure to good food rather than to one another, statistics regarding the occupational incidence of diabetes—"whenever and wherever conditions of life are easy, food abundant and relatively cheap over long periods, and when large numbers of individuals become accustomed to partake of food in excess of their requirements for the expenditure of energy, the frequent development of overweight and of diabetes is favored." In other words, those of sedentary occupation and large appetite are most likely to develop diabetes, those who labor the hardest and keep lean get it the least.

There are other influences than obesity that have to do with causing diabetes. Of these, racial peculiarities are the most outstanding. The high incidence of diabetes in Jewish people is proverbial. It has low incidence among the Chinese, Japanese and Negroes, and it appears to have rising incidence among the Irish. Factors like trauma, in-

fection, worry and arteriosclerosis do not appear important. This is about all that is known about diabetes and its etiology. The disease is a peculiar one, transmissible by inheritance, somewhat racial in character, afflicting fat people rather than thin, brought into being by an unknown factor, and perhaps more directly due to abnormal pituitary function than to abnormal pancreatic function, though pancreatic extract is the most useful therapeutic weapon at present available.

Can rational preventive measures be designed to operate against a disease about which, relatively speaking, so little is known? Joslin is optimistic. He is hopeful that the disease, to some extent at least, may be prevented by two barriers. If White and Pincus are right, a child cannot inherit a diabetic tendency from one diabetic parent alone but only from two diabetic parents, from one diabetic parent and a hereditary carrier, or from two hereditary carriers. The corollary is that to prevent diabetes, diabetic patients must not intermarry, or marry into families where diabetic carriers are known to exist, and they must remember that their children, too, must not marry diabetic persons or into diabetic families. As for obesity, Joslin says that it should be avoided generally, and particularly by the relatives of diabetic patients. Focus on the diabetic family, he says, for the prevention of the disease, remembering that all relatives, and especially the obese relatives, are the most susceptible. Hence, focus on the diabetic family to forestall intermarriage of diabetic carriers and to prevent obesity in all its members. Instruct each member not to marry into a diabetic family and never to allow his or her weight to go above the normal standard, in fact, after the middle of the fourth decade urge them to keep their weights 5 to 10 per cent below normal. If you can accomplish these things, you are doing all that can be done, in the light of present knowledge, to prevent diabetes.

I confess that I am a good deal less hopeful than is Joslin about the rationality of preventing diabetes. I present two cases to show why.

The first case is that of Mr. P. He is 56 years old, and a Yankee. He believes that his father died of "shock and diabetes," and he recalls having been told that a maternal uncle also had diabetes. Therefore, Mr. P. very obviously owns his diabetic genes by acquiring them in a most direct manner. To preclude his ever-developing diabetes, he should have been one of Peter Pan's "lost boys" and should never have been born, this would have been a hardship to him and his friends, for he has enjoyed life, been popular and accomplished much. Or possibly his parents should not have married each other, harboring as they did the power to transmit diabetes. The difficulty here is that Mr. P.'s father did not develop diabetes until he was an old man, nor did Mr. P.'s uncle. Mr. P.'s parents married when they were young, without estab-

lished diabetic family histories, knowing nothing of the disease and probably caring less and they lived happily together for a great many years. They brought contentment and sunshine into other people's lives for they were generous citizens. It would have been a loss to many people and even to all New England if in order to prevent a theoretically possible son from developing a theoretically possible diabetes, they had not married.

Mr P inherited another interesting tendency. Both Mr P's parents were stout people, and Mr P himself seemed doomed to a stout build. I have known him for nearly 50 years and can testify that during this last half century he grew from a stout little boy into a stout, thick-set, muscular young man, and has mellowed into a stout, thick-set older man. For the last 40 years he has been actively interested in all forms of physical exercise. He has played games regularly and violently. He has never been a gross eater, and has watched his weight with care. In fact, since 1908 he has kept a systematic record of his weight, not wishing to become too stout. During these 30 years his weight has fluctuated between a low point of 205 and a high point of 235. He has found that when he weighs too little he does not feel well and that to suit

been. The urine contained 1 per cent of sugar and the blood sugar concentration was 250 mg. per 100 cc. in other words Mr P had developed diabetes under my eyes.

Could the diabetes have been prevented? As has been said obviously not allowing Mr P to be born would have been one method, not altogether satisfactory for many reasons. Could his diabetes have been prevented by not allowing him to weigh so much? There is no way to answer this question with assurance. On the one hand are Joslin's statistics, which suggest that for Mr P to have avoided obesity would have been wise. On the other hand is Mr P's own experience, suggesting that had he kept his weight down he would have not felt well or have been so active as he proved to be, and thus would not have accomplished so much in life or have been so happy, and it is a dangerous doctor who is willing deliberately to gamble with the happiness and effectiveness of his patients' lives unless he knows exactly what he is doing.

Finally, there is evidence for thinking that one's type of body build is largely an inherited characteristic. Mr P with diabetic genes also inherited obesity genes. Thus, as he grew up had he kept his weight down by under-eating he still would have been a stout, thick-set individual, to be sure an artificially thin one, but nevertheless by constitution the same stout, thick-set individual he was designed to be and, so far as anyone knows, with the same inherited health liabilities. It seems to me that there is no certainty, with such inherited tendencies toward diabetes and toward body build that Mr P could have avoided the one by attempting to manipulate the other. In other words, I doubt whether his diabetes was preventable.

I cannot help raising one more question. Assuming that Mr P's diabetes could have been prevented, would to prevent it necessarily have been wise? He had fifty-five years of active, happy living as a prediabetic before the disease eventually became apparent. He took no particular care of his health during these years, kept largely out of medical hands and took life as it came. You will remember that a great many years ago Osler¹¹ wrote a most delightful paper, "On the Advantages of a Trace of Albumin and a Few Tube Casts in the Urine of Certain Men above Fifty Years of Age." I am sure that Joslin could write an equally appealing paper stressing the advantages to certain persons above that age line of a little glycosuria, for once patients of this age are conscious of the symptoms of diabetes, they seek medical advice and begin to take care of themselves. Mr P is a case in point. Very simple dietetic restriction after the diabetes made itself known, em

FIGURE 1 The Weight Curve of Mr P during the Period of Time He Was "Prediabetic"

his own particular sense of well-being, he can do most, with least fatigue, at a weight level of around 230 pounds. Between 1908 and 1936 he had scarcely a day's illness. Besides being active in athletics, he also has been in a position of considerable business responsibility and to all intents and purposes has been well.

Mr P consulted me professionally in June, 1936. At that time he did not have diabetes the urine was sugar free, and after an ordinary meal the blood sugar concentration was 100 mg. per 100 cc. He came to see me again on November 29, 1938. In the interval between the examinations he had gained 10 pounds in weight and had been feeling perfectly well leading his usually active life and having no physical complaints whatsoever. He told me that in August, 1938 he first became conscious of the fact that he was getting up two or three times at night to urinate. He denied any excessive thirst. He said that his appetite was as usual and no greater than it ever had

phasis on the importance of reasonable care and insistence on occasional check-ups have resulted in the disappearance of diabetic symptoms, slight loss in weight and an increased sense of well-being. The discovery of diabetes in Mr P's case will, I hope, prove to be a form of life insurance for him, as a result of which he will live longer and more happily than he could have done without it! You

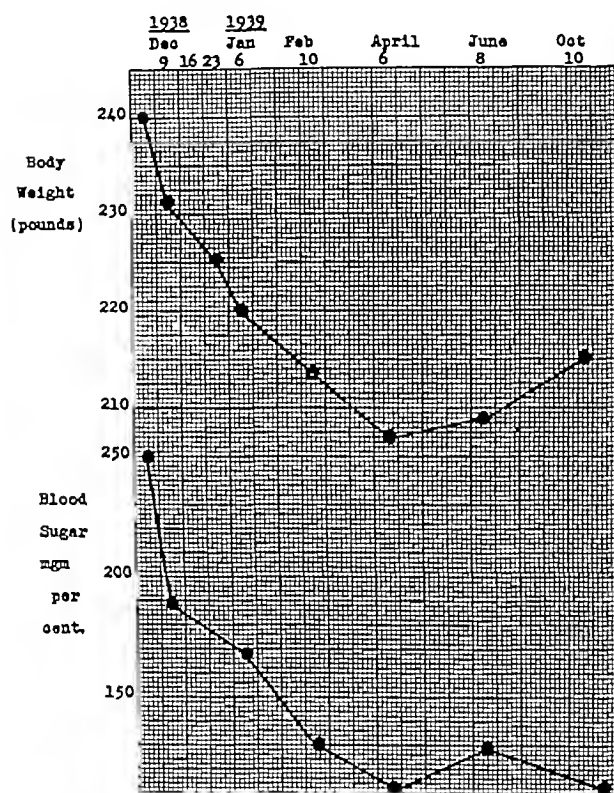

FIGURE 2 *The Advantage of a Little Sugar in the Urine of a Man above Fifty Years of Age*

Moderate diet restriction results in weight loss, an increased sense of well-being and a disappearance of hyperglycemia and glycosuria. Diabetes may be a good form of life insurance

can see that I am by no means convinced, even had it been possible, that to prevent diabetes here necessarily would have been judicious

The second case is rather different. Mrs. R. is a Jewish lady, 59 years old, whom I first saw 4 years ago. She consulted me for ill-defined aches and pains. A sister had died of diabetes, so that Mrs. R. presumably was to be regarded as a potential diabetic carrier. She was obese, too, for she weighed 162 pounds, which, for her height and age, made her nearly 30 pounds overweight.

The first specimen of urine which was examined contained 2.5 per cent of sugar. However, a fasting blood-sugar sample had a concentration of 140 mg per 100 cc., a fasting urine sample was sugar-free. I was uncertain whether she had diabetes, but on general principles advised her to follow a restricted carbohydrate diet. I saw her 5 months later, she had lost 7 pounds, and had a blood sugar concentration of 110 mg per 100 cc., and an entirely sugar-free urine.

I lost track of her for a year. Then, however, she returned with symptoms suggesting gallstones. She weighed 150 pounds and looked very well. Four samples of urine were examined, two were sugar-free, and two showed the faintest trace of sugar. Stupidly enough, my interest was so focused on the gall bladder, which proved to be normal, that I neglected to determine the blood sugar level.

A few days ago, more than 3 years after the last note, I again saw her. She weighed 154 pounds, thus revealing no great change in weight, she had no diabetic symptoms but called on me more for old times' sake than for any other reason. The urine had 5 per cent of sugar and the blood sugar concentration was 290 mg per 100 cc.

Could her diabetes have been prevented? At present we have the scantiest information regarding how the attack of what we recognize as diabetes commences. Both Mr P and Mrs R are interesting on this score. Mr P apparently developed clinical evidence of diabetes with relative acuteness, whereas Mrs R developed it so insidiously as to make it impossible to demarcate the nondiabetic part of her life from the diabetic.

I am in hopes that knowledge can be accumulated so that it may be possible to know more than is now known about the factors which make diabetes apparent. I am in hopes that more authenticated cases can be reported like the dramatic one of Wallach's,¹² which he described in 1866. There was a young chemist, it appears, who was in the habit of testing his own urine at least once a week, using it as a control against pathologic liquids whose sugar content was under analysis. His urine always was sugar-free. He had an attack of bronchitis, and as he was convalescing he began very suddenly to pass large quantities of urine, drink large quantities of water and lose weight. Wallach examined him and suspected diabetes, but, he wrote "Because the full significance of this illness was so well known to my patient, tact forbade me to test his urine immediately." A few days later the young chemist made his own diagnosis. Wallach goes on "I found my patient out of bed, sitting at his worktable, holding in his trembling hand a test tube with his own urine in it and with an ominous precipitate at its bottom." The poor chap died in coma within a few weeks of the first onset of symptoms. Here was a case beginning acutely. I, too, have seen a patient thought not to have diabetes when first she was studied who subsequently developed it with such apparent suddenness that she could remember almost the day and hour when symptoms began.

I believe that the question of preventing diabetes cannot be discussed any more logically or with any more conviction than I have discussed it here until more is known of the fundamental nature of the disease. It is to investigate this that I want help from my colleagues. Therefore,

I take this opportunity of begging them to send me case reports through which to study the possible factor or factors that induce the clinical manifestations of diabetes large numbers of case reports on patients well studied when they were nondiabetic, with accurate accounts of the manner in which diabetic symptoms seemed first to become apparent. A large group of cases analyzed from this approach not only might enable one to classify diabetes more accurately than can be done at present, but also might perhaps bring to light some common factor running through the group which would appear to define the agent that explodes the disease in the predisposed individual. Could the beginning of diabetes be recognized and the trigger that fires it be identified, better means for prevention might be developed than those advocated by Joslin. At present, in most cases, lack of knowledge makes the assured preventability of diabetes very elusive.

ENGORGEMENT OF THE PULMONARY VEINS BY EXTENSION OF CARDIAC ENLARGEMENT POSTERIORLY*

Relation to Postural Dyspnea in Cardiac Patients

WILLIAM D. REID, M.D.†

PORTSMOUTH, NEW HAMPSHIRE

ENGORGEMENT of the pulmonary vessels in cardiac patients is usually attributed to failure of the left ventricle. The latter causes an increase in pressure in the left auricle, and this pressure in turn is exerted backward on the pulmonary circulation. This theory of backward pressure, however, has not appeared to be fully satisfactory. Attention tends to be too exclusively centered on the heart, and adequate consideration has not been given to the mechanical relations of the heart to the structures behind it. It is the purpose of this article to present reasons in support of the conception that compression of the pulmonary veins and of the lungs by extension of cardiac enlargement posteriorly is a more valid explanation of engorgement of these vessels and of dyspnea of cardiac origin.

ENGORGEMENT OF THE PULMONARY VEINS

Overfilling of the pulmonary veins has become practically synonymous with failure of the left

ventricle, as may be documented by a citation from a recent book.¹ Thus

The clinical picture of isolated insufficiency of the left side of the heart is characterized by signs and symptoms resulting from engorgement of the pulmonary circuit in the absence of systemic venous engorgement and its consequence, such as edema and swelling of the liver.

The mechanism by which the engorgement of the pulmonary veins is produced is usually explained by what is known as the "back-pressure theory." Apparently this theory was developed approximately a century ago.

Corvisart,² one of Napoleon's physicians, in 1812 stated

It is possible that, in diseases of the heart, the difficulty of breathing proceeds entirely from the mechanical compression of the lungs, by the enlargement of the heart, or the evolution of an aneurysmal tumor; this is true in some cases, but in a greater number the difficulty of respiration appears to belong solely to the accumulation of the blood in the vascular system of the lungs, from the embarrassment which it suffers on returning into the cavities of the heart, deranged wholly or partly in their natural organization.

Hope,³ an English physician in his book published in 1842, further developed this conception, and to

*From the Cardiac Research Clinic, Massachusetts Memorial Hospitals, Boston.
†Formerly assistant professor of cardiology, Boston University School of Medicine, and cardiologist, Massachusetts Memorial Hospitals.

him is generally credited the origin of the back-pressure theory. He wrote

But when the distending pressure of the blood preponderates over the power of the ventricle, its contents, from not being duly expelled, constitute an obstacle to the transmission of the auricular blood. Hence the auricle becomes over-distended, and the obstruction may be propagated backward through the lungs to the right side of the heart, and there occasion the same series of phenomena

Harrison⁴ in his recent book supports the back-pressure theory

However, a considerable number of writers, among whom may be mentioned Mackenzie,⁵ Lewis,⁶ Starling⁷ and Wiggers,⁸ do not accept this explanation, save in cases of marked stenosis or insufficiency of the mitral valve. It should be noted that Hope's description contains the word "propagated", and a reasonable interpretation of this is that the pressure is transmitted backward through the blood in the pulmonary veins. Corvisart's words, as I understand them, are limited to emphasizing the importance of cardiac enlargement and engorgement of the vascular system of the lungs, "from the embarrassment which it suffers on returning into the cavities of the heart." The quotation does not elucidate the exact mechanism of the embarrassment.

I have found it difficult to be satisfied with the applicability of left ventricular failure to attacks of acute edema of the lungs experienced by patients with chronic arterial hypertension, when prior to the attack they have been in bed and asleep, whereas in the daytime they may have been ambulatory and relatively free of symptoms. Why do such left ventricles fail, even though they be abnormal, when the patient is in bed? Rest in bed is usually believed to be the best treatment for an individual with cardiac insufficiency. Since left ventricular failure is diagnosed in life by its effects, namely by engorgement of the pulmonary vessels, one tends to consider what there may be in the horizontal posture that might cause overfilling of the pulmonary vessels.

When the patient lies down, the lessening of the operation of the force of gravity causes a better return of the blood from the inferior vena cava to the right heart. This blood is promptly forwarded to the lungs by the contraction of the right ventricle, the Bainbridge reflex may be in operation in this situation. Thus, there is reason to believe that there is a generous inflow into the pulmonary vessels when the patient is in a horizontal position. Furthermore, when he lies down the heart naturally gravitates backward and rests more on the structures behind it (below it, in the horizontal position), if the heart be enlarged, it might conceivably exert a more than normal pres-

sure on its bed. It therefore becomes pertinent to consider the anatomic relations and physiology of the retrocardiac structures.

THE RETROCARDIAC SPACE

The retrocardiac space anatomically comprises part of the middle and posterior mediastinal spaces.

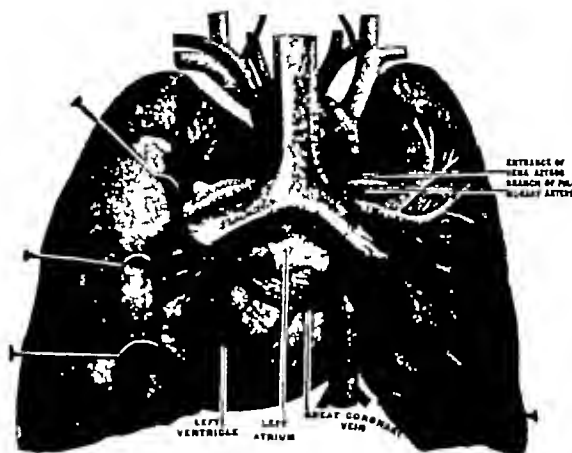

FIGURE 1 *Pulmonary Veins Seen in a Dorsal View of the Heart and Lungs*

The lungs have been pulled away from the median line, and a part of the right lung has been cut away to display the air ducts and blood vessels. (Reproduced from Anatomy Descriptive and applied Henry Gray From the new American edition [Philadelphia Lea and Febiger, 1913] By courtesy of the publishers.)

In brief, it is the area between the posterior surface of the heart and the front of the vertebral column.

The pulmonary veins pass through it, as they return the oxygenated blood from the lungs to the left auricle of the heart. Each venous trunk is formed by the union of the lesser radicles in the lungs and is about 1.5 cm. in length, both are approximately of the same caliber. The right pulmonary veins pass behind the right auricle and ascending aorta and superior vena cava, those on the left pass in front of the thoracic aorta. These veins are thin-walled, and contain no valves.

The inner or mediastinal surface of the lungs presents a deep cavity that accommodates the pericardial sac. Above and behind this concavity is a triangular depression termed the hilus, where the structures forming the root of the lung enter and leave it.

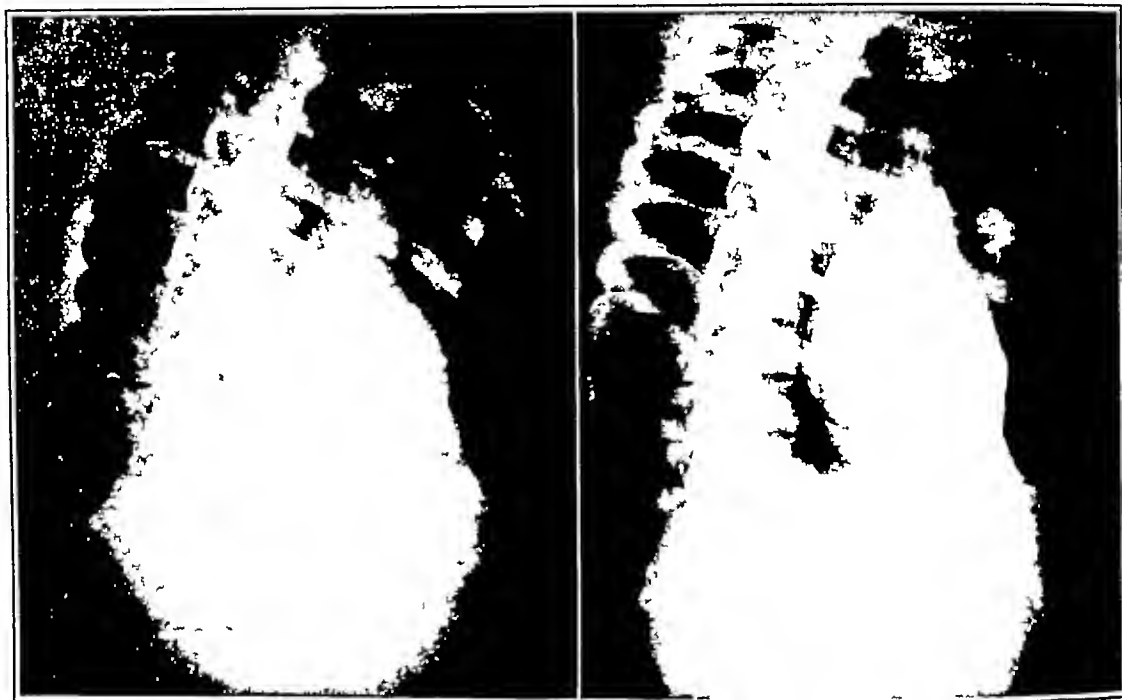

RESPIRATORY MOVEMENTS OF THE HEART AND LUNGS

Shipley⁹ states that the heart is attached to both lungs by means of the pulmonary artery and veins. It is also attached to the diaphragm at its central tendon by the pericardial covering of the inferior vena cava as it pierces the diaphragm. The heart is firmly fixed to the aorta, which is said to move

THE POSTMEDIASTINAL SYNDROME

There is a condition, sometimes termed the postmediastinal syndrome, in which dyspnea is an outstanding symptom. Tumors invading the posterior mediastinum are the usual finding at necropsy. Dyspnea of such causation is not infrequent in Hodgkin's disease. A recent article¹⁵ describes such a patient in whom dyspnea and

large pericardial effusion who automatically assume what is sometimes termed the "position of Allah," more accurately designated by the French as the *signe de la prière mahometane*. It is practically a knee-chest position. There are also those patients with huge hearts who cannot sleep save sitting in a chair, often leaning forward on the back of another chair or on another person in

A

B

FIGURE 4 Radiographs to Show Relation of Heart to Spine

A—at full expiration, B—at full inspiration The subject was a normal boy, aged sixteen years

severe asthmatic symptoms supervened when he lay on his left side. Relief was gained when he turned to the right side. A mass in the mediastinum was present.

French¹⁶ lists the causes of the postmediastinal syndrome as follows: aneurysm, a large heart, new growth, hydrothorax with marked displacement of the heart and enormous distention of the abdomen by ascites, tympanites and large tumors. He states that the chief reason why a very large heart or thoracic aneurysm may produce orthopnea, even when signs of cardiac insufficiency are absent, is that when the patient lies down there is less distance between the sternum and the vertebrae than when he sits up. The cause for the orthopnea is thus mechanical: there is more room to accommodate the abnormal mass when the patient sits up. In some cases he may be able to walk about without distress in the daytime, and yet be unable to lie down at night.

The foregoing reminds one of patients with a

front of them. May not both these conditions be due to the relief obtained by lessening the pressure on the structures back of the heart?

There are still other patients who experience severe dyspnea when they assume some particular position in bed. The condition has been long known and has been recently restudied.¹⁷ It is sometimes known as trepopnea. The particular position which causes severe dyspnea varies with different patients. If trepopnea be due to pressure of an enlarged heart on its bed, or on the structures behind the heart, it is reasonable to assume that the differences in the degree and type of cardiac enlargement might account for the variations in the posture that induces the dyspnea. Thus, the left auricle is enlarged in mitral lesions and the left ventricle in chronic arterial hypertension and lesions of the aortic orifice, sometimes enlargement involves the heart as a whole.

Patients with congestive failure often show engorgement of the pulmonary vessels when exam-

med radiographically. Following rest and digitalis the lung fields may clear and the patient improve. It is well known that a failing heart is prone to be dilated and that digitalis lessens the dilatation. In

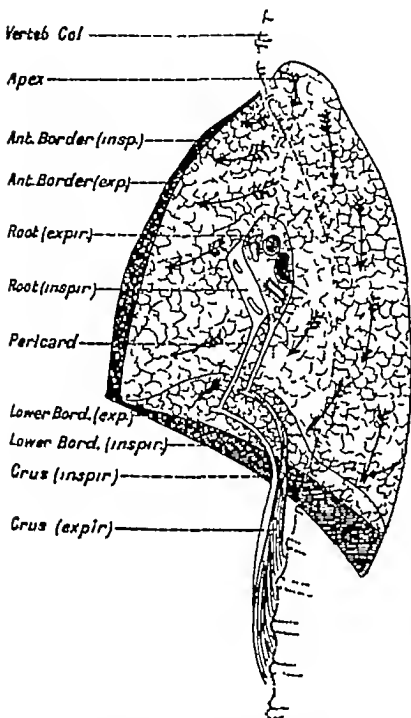

FIGURE 5 Mediastinal Aspect of the Right Lung to Show the Respiratory Movement of the Hilus

The crus of the diaphragm is also indicated and its attachment to the hilus of the lung through the pericardium. The arrows indicate the direction of the respiratory movement of the various parts of the lung (Reproduced from "The Mechanism of Respiration in Man" [Arthur Keith] in *Further Advances in Physiology* [New York: Longmans Green and Co. 1909]. By courtesy of the publishers.)

such a case the compression of the pulmonary vessels would be relieved, and with removal of the obstruction the pulmonary veins would be expected to cease being engorged.

POSTURAL DYSPNEA IN A SERIES OF PATIENTS

A series of cardiac patients have been closely questioned regarding the occurrence of dyspnea while they were in bed, their answers correlated with the fluoroscopic evidence of the backward

extension of their hearts. As controls there were selected other patients with proved disease of the heart and usually with some degree of cardiac insufficiency, but whose dyspnea was unrelated to posture.

There were 53 patients in all—17 with postural dyspnea and 36 without it. The former were all found to have marked extension of the heart backward into the retrocardiac space, whereas but 1 of the control cases had marked encroachment on the retrocardiac space. Some further details will be given, designating the two divisions as Groups 1 and 2.

Group 1 Fourteen patients had the predominant enlargement in the left ventricle, in 2 others it was mainly in the auricles, and in the remaining 1 the enlargement involved both cardiac chambers. Five patients reported that a particular position caused dyspnea more readily—4 the left lateral and 1 the right lateral position. Two of the 4 left lateral patients found the position impossible to maintain, they were definite examples of the trepopnea described above. Five other patients and 1 of those experiencing trepopnea were subject to paroxysmal attacks of dyspnea at night.

Group 2 All 36 controls had cardiac enlargement. In 17 cases the retrocardiac space was clear, in the remaining 19 the space was encroached on from slight to half its normal area, with 2 exceptions. In one of these the encroachment exceeded an estimated half of the retrocardiac space, in the other it was marked (this patient had a capacious and deep chest). As in Group 1 the encroachment was usually ventricular, the figures being left ventricle, 16 cases, left auricle, 2 cases, and pericardial effusion, 1 case. One of the group had had postural dyspnea three weeks previously, but it had disappeared at the time of the fluoroscopic examination. Two patients reported that if they lay on the left side they experienced symptoms other than dyspnea, in the first case it was anginal pain, in the second it was described as "grinding and palpitation." Still another patient found a particular position disturbing that is, anginal pain was prone to appear if he lay too flat.

Subject to the proviso that the number of patients examined for the purpose of correlating postural dyspnea with fluoroscopic evidence of backward extension of the heart was small, certain facts stand out. All patients with postural dyspnea were found to have marked encroachment on the retrocardiac space, usually by the left ventricle, whereas but 1 patient with a similar degree of encroachment failed to experience postural dyspnea. Encroachment on the retrocardiac space to a les-

ser degree — up to half its estimated* area — was common in cardiac patients not subject to postural dyspnea. The detection of 2 cases of definite trepopnea in so small a group was a surprise. Some evidence was also obtained regarding the relative frequency with which a particular posture is more disturbing to the patient. Certain data were not essential to the diagnosis of these cardiac patients and so did not appear in their clinical records, but were obtained when suitable questioning was employed.

DILATATION OF THE LEFT AURICLE

Some further information was also sought as to whether the back pressure was exerted from the cavity of the left auricle directly into the lumen of the pulmonary veins or by compression of these veins. When the heart is removed from the body at autopsy there are usually one or more sizable holes in the posterior wall of the left auricle. These are clearly an artefact. However, if the inside of this auricle be examined *in situ* it is found that the pulmonary veins are so arranged as to give some support for the conception that when the auricle is dilated a fold of its wall may close the orifice of the pulmonary veins. A situation may occur that is analogous to that of the urinary bladder, in which distention is said to cause a fold of mucous membrane to seal the urethral outlet and lead to further distention.

It is known that the left auricle is prone to distend, and it is difficult to conceive how this takes place unless the cardiac chamber be subjected to an internal distending pressure. It is likewise difficult to inflate a paper bag if there are holes in it. The capacity of the pulmonary venous system is so great that it is improbable that both the left auricle and the pulmonary veins are distended by blood driven backward, as when the mitral valve is incompetent.

COMMENT

It is appreciated that the back-pressure theory, based on left ventricular failure, has served to explain much that concerns the heart. The theory offered in this article differs less than one might think at first. The main point is that there is a hindrance to onflow by a mechanical compression of the pulmonary veins by cardiac enlargement. This conception appears more plausible in relation to postural dyspnea. When the patient lies down the structures that in the upright position are posterior to the heart become the bed for it, in other words, the enlarged heart lies on the pulmonary veins and their radicles.

*I am responsible for these estimates. I acknowledge the assistance of the roentgenologists of the hospital.

Dyspnea in cardiac patients is prone to be exertional or postural. Figures have been cited in order to emphasize the greatly increased volume of blood flow that takes place in response to exertion, and it is understandable that some obstruction to onflow, such as is present in mitral stenosis, for example, might then prove effective in damming back the flow through the pulmonary veins. An unfavorable posture, such as lying down, might likewise be effective in damming the flow, but might show more variance and develop more slowly depending on the type of cardiac enlargement, and where and to what degree it exerted pressure.

It was believed at first that encroachment on the retrocardiac space might give all the essential information regarding backward extension of the heart. However, it soon became apparent that examination of this space was merely a guide. There are probably other factors, such as posterior extension of the heart elsewhere than directly toward the spine, the position of the diaphragm (Fig 6), the amount of mobility in the thoracic wall and the size of the thorax as a whole. The reader is cautioned not to interpret the conception of pressure as being exerted solely on the pulmonary veins just before they reach the auricle, — they are stated to measure but 1.5 cm in length, — but to understand it as including their radicles, as they bring blood to the hili of the lungs.

Backward enlargement of the heart, particularly the left auricle, is credited with exerting pressure that causes such effects as aphonia, dysphagia and hydrothorax. Why may it not also so press on the pulmonary venous system as to cause engorgement of these veins? That the left auricle may compress even the superior vena cava appears from observations by Cossio and Berconsky¹⁸ made during the catheterization of the right auricle in man. Parenthetically, it may be pointed out that the distention of the cervical veins in their patients was not evidence of failure of the right ventricle and back pressure to the systemic veins, heart failure was absent in the cases studied.

Consideration of the findings in the series of patients studied for the possible correlation of encroachment of cardiac enlargement with the presence of postural dyspnea makes it evident that there is a considerable margin of safety, for more than half of the group not subject to postural dyspnea were found to have encroachment up to half the estimated area of the retrocardiac space, and in 2 cases the degree of encroachment was even greater.

There are undoubtedly factors inducing dyspnea other than engorgement of the pulmonary venous system, I refer to various reflexes of nervous origin.

and chemical changes operating on the respiratory center. These are adequately discussed in the textbooks of physiology. The purpose of the present article is to consider the significance of backward encroachment of an enlarged heart. En-

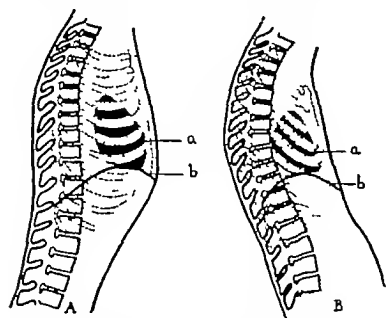

FIGURE 6. Diagrams Depicting the Effect of the Position of the Diaphragm and the Shape of the Thorax on the Relation of the Heart to the Vertebral Column. (Reproduced from *Body Mechanics in the Study and Treatment of Disease*. J. E. Goldthwait, L. T. Brown, L. T. Swann and J. G. Kuhns [Philadelphia] B. Lippincott Co. 1934.] By courtesy of the publisher.)

gorgement of the pulmonary veins, it is true, has been shown¹⁹ to induce dyspnea through a nerve reflex.

It is not asserted that the contents of this article have proved that engorgement of the pulmonary veins is caused by mechanical pressure exerted on their walls by backward extension of an enlarged heart, this is very difficult to prove. However it seems reasonable to suggest that physicians should not limit their thoughts to the heart in cardiac patients affected by dyspnea.

What can be done to improve the heart lung relation? For in a sense are we not all "heart lung preparations"? Some therapeutic possibilities come to mind. For example, should we not pay more attention to the posture of the patient? The use of a bed rest is a common procedure, but in patients who spontaneously assume the leaning forward posture should we not assist them, and make the position more satisfactory by the use of a pillow laid on a suitably placed table or chair? There are occasional patients in whom elevation on a bed rest gives but partial relief to dyspnea, but who will obtain greater ease if a leaning forward posture is prescribed. I have recently adjusted a hospital bed table in front of such patients and found that it lessened their dyspnea.

Crowding of the available space in the thorax by accumulations of fluid is an evident reason for

increased dyspnea. Removal of such effusions would seem to be indicated. An increased application of and a readiness to repeat thoracentesis have appeared to increase the comfort of our patients.

It seems reasonable to suggest the performance of the Brauer operation—the removal of the ribs over the precordia—in patients with marked enlargement of the heart and postural dyspnea, if the latter is unrelieved by medical therapy. The operation is believed²⁰ to be practically without danger, and can usually be performed under local anesthesia. It has been followed by great relief in 3 cases—1 reported by Morison²¹ in 1909 and 2 by Graham²² in 1929. Perhaps the significance of these operations has been lost sight of, since the Brauer operation was originally proposed for the relief of pericardial adhesions, although in these 3 cases it was performed for the purpose of decompressing an enlarged heart. I believe this operation to deserve further trial for the relief of the heart lung field.

SUMMARY

The conception is advanced that backward enlargement of the heart may cause mechanical compression of the pulmonary venous field and lead to engorgement of these vessels.

There are similarities to what is known as the posterior mediastinal syndrome.

Correlation of the fluoroscopic findings with the presence or absence of postural dyspnea resulted in considerable support for the above conception.

The production of engorgement of the pulmonary venous field by the compression caused by backward extension of an enlarged heart appears to explain postural dyspnea better than does the rather generally accepted theory of left ventricular failure.

REPORT ON MEDICAL PROGRESS

GASTROENTEROLOGY

CHESTER M. JONES, M.D.*

BOSTON

THE literature for 1939 concerning the gastrointestinal tract is so voluminous that it is obvious that only a portion of it should be included in this review. For that reason, the present article will concern itself solely with reports of various diseases of the small intestine and of the colon. In certain instances comments and discussions of various articles involve a consideration of surgical procedures. Gastrointestinal disease, however, can rarely be classified as purely medical or surgical, and it is the intention of the reviewer to emphasize the diagnostic and broader therapeutic aspects of the subject matter to be surveyed, without any particular consideration of detailed technical procedures.

SMALL INTESTINE

Although no single pathologic condition involving the small bowel, with the exception of duodenal ulcer, is of great numerical importance, the aggregate of all conditions involving the duodenum, jejunum and ileum is of real clinical moment. With the advent of more precise methods of studying small-bowel physiology and improved x-ray technique, it is quite justifiable to comment on the various conditions involving this portion of the digestive tract. It is important to recognize that diagnosis of small-bowel disease primarily depends on the ability of the clinician to suspect its existence, inasmuch as routine roentgenography rarely demonstrates lesions of the jejunum or ileum. It should be stressed, therefore, that any history of abdominal distress or discomfort that tends to localize itself in the region of the umbilicus should raise the suspicion of disease of the small intestine, and should afford the basis for systematic x-ray stud-

ies of this region by repeated fluoroscopic and film examinations, made at hourly intervals.

Megaduodenum is a condition that should be diagnosed only after careful study and only with an exact knowledge of the typical x-ray findings. Sturtevant¹ describes in detail the x-ray criteria for such a diagnosis. Duodenal antiperistalsis, duodenal stasis, violent duodenal peristalsis and the "writhing duodenum" are the x-ray findings to be encountered in this condition, which, as a rule, is of little clinical significance. A discussion of the symptoms that sometimes occur can be found in an article by Weiss,² who considers the etiology of megaduodenum and reports 6 cases occurring in members of the same family during three generations. He correctly comments on the fact that the condition may be asymptomatic and quite rightly stresses the importance of very conservative therapeutic measures.

Duodenal diverticula are not uncommon and are almost always not the cause of symptoms. That they may occasionally cause symptoms suggestive of ulcer is indicated in the report by Boland,³ who describes a death due to an acute perforation of a duodenal diverticulum which occurred at the usual site, namely the second portion of the duodenum. Another report of somewhat similar nature is that by Schunk,⁴ who describes the traumatic rupture of a jejunal diverticulum. It should be stressed, however, that as a rule such diverticula cause no symptoms and do not warrant surgical treatment.

An unusual accident is that mentioned by Roach,⁵ who describes a fatal hematemesis due to a rupture of an abdominal aortic aneurysm into the third part of the duodenum. The history in this case was suggestive of an old duodenal ulcer, with symptoms extending over a period of ten years and even including one attack

*Assistant professor of medicine, Harvard Medical School; physician, Massachusetts General Hospital.

of bloody vomiting. The patient finally entered the hospital, and as on previous occasions, x ray films demonstrated a deformity in the region of the duodenal cap, apparently due to external pressure. A sudden fatal hemorrhage occurred, and autopsy revealed no duodenal ulcer but an erosion through the duodenum from a contiguous dissecting aneurysm of the abdominal aorta.

Disturbances of the jejunum and ileum are caused by a variety of diseases. A satisfactory and somewhat routine summary of these causes can be found in an article by Kiefer.⁶ Inasmuch as most of the symptoms of small-bowel disease are associated with the existence of partial obstruction, it is of importance to refer to articles dealing with various possible causes. One interesting cause is that reported by Havens,⁷ who discusses a case of intestinal obstruction caused by the use of colloidal aluminum hydroxide. This patient died of intestinal obstruction following a seven-day treatment of constant drip of this preparation. Such a serious outcome is rarely to be anticipated, but the frequent use of aluminum hydroxide gel as a treatment of ulcer warrants the suggestion that the preparation should be used with a good deal of care because of its tendency to provide the source for a nonabsorbable solid mass. Adamson and Hild⁸ also report a case of small bowel obstruction due to a mass, in this case occurring in an infant thirty six hours after birth the ileum being found to be packed with in spissated waxy meconium. Although the condition is rare, 22 cases have already been reported.

Intestinal obstruction due to intraluminal foreign bodies is really not uncommon, and the article by Storck, Rothschild and Ochsner⁹ is of value inasmuch as it reviews a total of 875 cases, exclusive of hernia, neoplasm and peritonitis. In this group, 51 cases were due to foreign bodies, of which the commonest were fecaliths and the next commonest, masses of intestinal parasites. The incidence of obstruction due to intestinal parasites naturally varies in different sections of the country, but the fact that they may cause intussusception, intestinal spasm and perforation of the bowel is worthy of emphasis. The article is complete and well worth careful reading.

Gallstones have long been known to be the source of intestinal obstruction, and the report of Wakefield, Vickers and Walters,¹⁰ although presenting no new material, is of interest in this connection. The authors point out that in every case the gallstones appear to have reached the intestinal tract via a cholecystoenteric fistula. The fistula may not remain patent after the passage of the gallstones. It is significant that some of

the patients described had recurring attacks of intestinal obstruction prior to the onset of complete ileus. McQueeney¹¹ records 2 rather unusual cases in which the patients survived gallstone obstruction of the bowel and lived with persistent intestinal biliary fistulas for fifteen and nineteen years respectively.

A rare benign cause of intestinal obstruction is that reported by Pachman,¹² who adds 3 cases to 33 others already reported in the literature as due to enterogenous intramural cysts. In his cases, the intestinal cysts were the cause of obstructive symptoms and occurred in children under one year of age. Shaw¹³ reports 5 cases of polyposis of the small intestine, a relatively rare clinical entity but important because of the tendency to malignant degeneration.

Lieber, Stewart and Lund¹⁴ reviewed the literature on carcinoma of the prepapillary portion of the duodenum in a study of 222 cases, including 17 of their own. This very dangerous condition is uncommon but it is necessary to point out that in most of the cases reported inadequate x ray studies had been performed with the result that only 17 per cent were correctly diagnosed prior to operation. The operative mortality in this condition is extremely high, with jaundice occurring in practically all cases, pain in about two thirds and fever in about one third. An excellent summary of the subject of tumors of the small intestine is that by Cohn, Landy and Richter.¹⁵ It contains an excellent bibliography, with a good review of the literature. The frequency of small bowel malignancy varies in different statistics, and the subject is also well covered by Medinger,¹⁶ who reviews the cases from the New England Deaconess and the Palmer Memorial hospitals. According to Medinger, malignant tumors of the duodenum and ileum appear to be slightly more frequent than those of the jejunum. Carcinoma occurs most frequently in the duodenum and jejunum and sarcoma in the ileum.

Leiomyosarcoma is extremely rare, only 6 cases being mentioned in the literature, 1 a recent case reported by Foshee and McBride.¹⁷ Another form of tumor that is uncommon but worthy of comment is the argentaffine tumor, which for the most part is found in the region of the appendix. Several individual cases are reported, but the series of 72 cases mentioned by Porter and Whelan¹⁸ is of particular interest. The incidence of the tumor can be readily seen in that only 72 cases were found in a total of 26,000 surgical specimens examined. In addition to these tumors in the appendix, 2 were found in the stomach, 1 in the gall bladder, 1 in the duodenum and 8 in the

small bowel. None of the appendiceal tumors were malignant, but of the 8 argentaffine tumors of the small intestine, 3 were malignant.

The importance of Meckel's diverticulum as a cause of intestinal obstruction is well known, as is the fact that not infrequently the diverticulum contains gastric mucous membrane. The case report by Martin¹⁹ describing an intussusception from such a diverticulum contains nothing new, but the accompanying résumé of the literature is presented in a well-organized fashion and is an unusually complete description of this form of small-bowel disease. The discussion includes a consideration of the condition, the acute and inflammatory process associated with Meckel's diverticulum, ulceration, perforation, hemorrhage and obstruction.

Hyperplastic tuberculosis of the small bowel is a recognized but rare cause of obstruction. Because of its infrequency, it is not generally recognized as a possible explanation for symptoms of intestinal obstruction, and for this reason the report by Caplan and Roantree²⁰ is worthy of consideration. Mesenteric adenopathy is well known to be a cause of symptoms simulating appendicitis or partial obstruction of the ileum, and may be a manifestation of tuberculous nodes or of some nonspecific inflammatory involvement. A complete description of the abdominal syndromes from adenopathies of the mesentery is presented by Parini,²¹ who discusses differential diagnosis and very properly concludes that surgical interference is usually indicated only in acute forms in the presence of intestinal obstruction due to acute supuration of the nodes. Too frequently, the demonstration of calcified lymph nodes throughout the mesentery is taken as an adequate reason for surgical intervention, although it not infrequently happens that symptoms are due to other causes or are unrelieved by surgical procedures.

An unusual form of intestinal obstruction is that reported by Orr,²² who records 2 cases associated with mechanical injury to the spine. The difficulties of diagnosis are obviously increased with a cast covering the entire abdomen, the pain being attributed in one of the cases to a broken back, and in the other to a paralytic ileus and pressure of the cast. In neither case was the diagnosis of intestinal obstruction adequately considered.

Intestinal intussusception in infants as a cause of small-bowel obstruction is well recognized. The report of Garcia²³ on 29 such cases is of interest, largely as a review of the physical findings and the technical surgical procedures necessary to treatment. Intussusception in adults is less common, however, and for this reason the short re-

port of Miller²⁴ is of interest as indicating that it may occur in the presence of benign tumors of the small bowel or in relation to Meckel's diverticulum. A somewhat similar report by Mendelson and Sherman²⁵ also emphasizes the various causes that may lead to intussusception of the small bowel or, for that matter, of the large bowel.

In discussing acute obstruction of the small bowel, Holt²⁶ emphasizes the obvious necessity of early diagnosis and treatment. Because of the appearance of the irreversible circulatory changes that take place, he makes out a good case for the therapeutic value of intestinal decompression and subcutaneous salt solution prior to actual surgery for the condition. A more valuable discussion is that of Gendel, Fine and Rosenfeld,²⁷ who record the results of experimental acute intestinal obstruction in dogs on blood plasma volumes. These authors stress the importance of the early progressive loss of blood plasma, which may reach a figure of 36 per cent within four to six hours, with a loss of plasma volume of as high as 55 per cent within twenty-four hours after the production of the obstruction. Such a loss of plasma, which is equivalent to around 3 per cent of the body weight, is more than sufficient in itself to cause death, and occurs particularly in those cases in which strangulation is added to obstruction. Blood-pressure readings apparently are not so accurate a guide to the patient's condition as are the hematocrit readings with their direct evidence of the loss of plasma volume. The administration of adequate quantities of plasma by the intravenous route is recommended by these authors, with sound reasons for advocating such a measure.

APPENDICITIS

That appendicitis still presents a challenge to the medical profession is obvious from the number of articles that have appeared during the past year on this subject. An increasing mortality from this condition emphasizes the necessity of educating the public against the continuous use of cathartics for abdominal pain and against delay in the diagnosis and treatment of acute abdominal pain, not only in the right side but also in the middle of the abdomen. This fact has been properly stressed by a rather forceful letter²⁸ in the *Journal of the American Medical Association*. The seriousness of the problem is apparent from the fact that approximately 16,000 deaths are reported in this country every year as due to acute appendiceal peritonitis. In Canada, appendicitis rates tenth as a cause of death.

The danger of delayed diagnosis is emphasized in an article by Kelly and Watkins,²⁹ who present

an interesting review of the results of 1000 consecutive cases of acute, simple and chronic appendicitis operated on within recent years, and contrast these with the results obtained in 1000 similar cases reported by them in 1931. The results in the latter series show no great variation from those previously reported, except for a sharp increase in the mortality rate noted in those classified as acute suppurative appendicitis. Under this classification there was a rise from a 9 per cent mortality in the first series to 23 per cent mortality in the second group. A similar increase in deaths from acute appendicitis was noted in an entirely analogous report by Quain and Waldschmidt^{30, 31} on two 1000-case studies reported in 1928 and 1934 respectively. They reported a mortality of 18.8 per cent during the depression years, as compared with a mortality of 10.0 per cent prior to that time. Kelly and Watkins believe that this rather alarming increase in mortality is due to a delay in operating because of economic reasons during the depression years and a tendency to use home remedies, including purgatives, before calling a physician. Meyer and his collaborators³² show about the same mortality rate at the Cook County Hospital in the years 1937 and 1938 as compared with the period from 1928 to 1932.

Numerous reports, such as those of Munroe,³³ Horsley,³⁴ Raffi³⁵ and Lundgren, Garside and Boice³⁶ seem to indicate that the mortality from certain groups of uncomplicated cases may be as low as 0.7 per cent. Perusal of these case reports however, suggests the possibility that these low mortality figures were encountered in the most favorable age groups, exclusive of children and older people, and quite probably in patients of the higher economic levels. Obviously, increased mortality rates are found in cases where delay has occurred and peritonitis is a complicating factor.

The treatment of over 100 consecutive appendicemias complicated by local or generalized peritonitis with non-drainage as recorded by Pickehl,³⁷ with a mortality of only 4 per cent, suggests that unusually great care was observed in the preparation and handling of individual patients. Some of the factors that may help lower the mortality are suggested by Wright, Aaron, Regan and Milch,³⁸ who report two small series of cases treated in 1935 and from 1935 to 1939, respectively. In all the cases there was diffuse peritonitis following perforation of the appendix. In the first group, the mortality was 45 per cent, in the second group, 12 per cent. In the first group the patients were operated on by six different surgeons, with no uniformity of treatment. In the second group three surgeons were responsible for the care

of the patients, and in their 60 cases it was concluded that the intelligent use of morphine, fluids, duodenal decompression and transfusions were of great effect in combating the hazard of peritonitis, with subsequent lowering of mortality.

The value of decompression by the Wangensteen technic is stressed by various authors, particularly where perforation has occurred. In children the need of immediate operation once the diagnosis has been established is stressed by numerous writers. In the uncomplicated cases, all the writers agree that the mortality is low. Thompson³⁹ discusses a group of 110 children with extra appendiceal extension, and expresses the belief that the chief factor in bringing about recovery is the nearly complete removal of fluid and gas from the distended paralytic or obstructed bowel loops. By careful attention to detailed preoperative measures, mortality was limited to 4.5 per cent in a group of 110 seriously ill children.

The importance of deferring operation in the presence of peritonitis due to ruptured appendix in children is discussed by Elman.⁴⁰ Decision to postpone operation, he thinks, depends not so much on the presence or absence or the degree of peritonitis as on the general condition of the patient. The amount of clinical toxicity obviously influences the mortality to a marked extent. In those patients with perforated appendices who were operated on at once, the mortality was extremely high, whereas in those operated on after careful treatment and a delay of from nine to twenty-four hours, the mortality was less than half as great. On the other hand, in the nontoxic group the condition was reversed, delay in operating apparently causing 15.0 per cent mortality as opposed to a mortality of only 3.5 per cent in those children operated on immediately. From these articles and from numerous others, it is obvious that most of the factors determining mortality are well known. Even in the most serious cases, however, sufficient delay with adequate preoperative treatment, including decompression of the distended small bowel and the proper use of fluids, tends to reduce deaths to a fairly reasonable figure. In passing it is of some interest to mention the case reported by Redon,⁴¹ if only to illustrate that at times appendicitis or acute intussusception may be completely reproduced by an allergic disturbance (Quincke's edema) with edema of the bowel. As a rule the diagnosis of appendicitis is simple, but such a diagnosis is not always warranted unless a fairly complete history has been obtained, which should include a few questions as to allergic disturbances.

The seriousness of "laxative induced peritonitis"

is brought out in an article by Bower, Burns and Mengle⁴² In this report the authors discuss the use of a concentrated *Clostridium welchii* antitoxin preoperatively or postoperatively as a means of localizing peritonitis Unfortunately no control figures are given, but the report is of theoretical and possibly of practical interest In this connection the paper by Bain and Feagles⁴³ is also of some interest These authors treated 100 cases of peritonitis from ruptured appendices and 15 other cases due to perforated viscera with intra-abdominal irrigations of peptone broth Apparently very favorable results were obtained, with a drop in temperature and pulse and a reduction in pus drainage The exact mechanism of such irrigations is discussed in terms of stimulation of the body-defense mechanism by foreign protein or stimulation of the formation of bacteriophage Such a maneuver is obviously in an experimental stage, but is of interest in relation to the work of Steinberg and others

Of further interest is the report by Carry, Brewer and Nicol,⁴⁴ who record the postoperative treatment of appendiceal peritonitis with sulfanilamide Twenty-six patients with general peritonitis and 15 cases of appendiceal abscess were treated postoperatively with sulfanilamide, with 3 deaths Of the patients who died, only 1 at necropsy still had general peritonitis of the lower abdomen Although the number of cases reported is too small to be statistically important, it will not be surprising if sulfanilamide or one of its derivatives proves of real worth in the management of these badly infected cases

An unusual complication of appendicitis is that reported by Parker⁴⁵ The patient was operated on for chronic appendicitis, and recovery was uneventful Three weeks after leaving the hospital the patient returned with a complaint of a rectal hemorrhage following a bowel movement Sigmoidoscopy was negative Two subsequent hemorrhages occurred, the last one of serious proportions Exploration revealed active inflammation of the cecum in the region of the stump of the appendix and a mass within the cecal wall, which on exploration was found to be an abscess cavity that had eroded into a large artery

ULCERATIVE COLITIS

Chronic idiopathic ulcerative colitis still remains an unsolved problem of great importance, and although studies as to its etiology are numerous, they are still unconvincing Two articles by Reed⁴⁶ present in summarized form the various views that have attracted attention as to the causation of this very grave condition Reed records the ob-

servations of Hurst, Thorlaxson, Felson and others on the relation between this condition and bacillary dysentery, and also considers the well-known studies of Paulson, Barger and Dack His own bacteriological studies are in accord with those of Paulson, who has concluded that as yet the disease has not been shown to be due to any demonstrable single infectious agent He stresses the need of considering bacillary dysentery, amebic dysentery and also other factors that are incident to the disease, such as psychogenic disturbances, deficiency states due to malabsorption and so forth He also points out the difficulty of accurate timing of surgical intervention, a fact that is well worth emphasizing The articles contain nothing new but are of some interest because the author reiterates most of the considerations that are generally accepted in relation to ulcerative colitis

One of the most significant contributions to an understanding of the subject is found in the brilliant observations of Lium⁴⁷ In experiments on dogs, by means of colonic implants he was able to demonstrate that mechanical stimulation, parasympatheticomimetic drugs or dysentery toxin causes spasm of the colonic musculature, with resulting damage to the underlying epithelial structure, hemorrhage and ulceration The mode of action of dysentery toxin in producing ulcerations of the mucosa is thus apparently due to the injurious effects of smooth-muscle spasm Hypersecretion of mucus was associated with increased muscular contractions at first, but later a thin watery secretion, inadequate for protective purposes, was observed, with resulting inadequate protection of the mucous membranes from trauma Lium discusses the possibility that ulcerative colitis may be conceived as a specific reaction to a number of influences that can initiate spasm of the colonic musculature These include possible hyperactivity of the parasympathetic nervous system, infections, such as bacillary dysentery, and vitamin deficiency Once the colon becomes spastic, it is potentially an organ that can produce damage to its own surface structures In analyzing the distribution of lesions observed in 6 fatal cases, Lium and Porter⁴⁸ conclude "It seems highly probable that ulcerative colitis is primarily a disease caused by intense muscular spasm and hypermotility and that, therefore, the distribution of the lesions follows a muscular pattern Whatever infectious element is present may well be due to secondary involvement of damaged areas caused by muscular overactivity" It is not difficult to draw an inference from a comparison between these striking observations of Lium and Porter and many of those cases of ulcerative colitis that appear to have their fundamental origin in an unstable and over-

stimulated autonomic nervous system. The changes visualized by Liem following the action of parasympathetic drugs are not dissimilar to those reported by White and Jones⁴⁹ and bear a direct relation to the clinical observations of Sullivan,⁴⁹ Murray⁵¹ and Alexander.⁵² on the importance of emotional factors in initiating this disease.

Clinical observations by Liem⁵³ on 8 normal individuals and 1 patient with ulcerative colitis are of interest in this connection. Measurements were made of contractility under measurable stimuli of the rectum, and the resulting rectometrograms indicated that the rectal contractions were much more powerful and prolonged in the presence of ulcerative colitis and were less amenable to relaxation by spinal anesthesia than in normal people. The importance of these continued contractions in the chronicity of ulcerative colitis is discussed. In this regard the studies of Barger and Jackman⁵⁴ are of interest therapeutically. They studied the influence of papaverine on the muscular tone of the intestinal tract. In their hands, papaverine, alone or combined with pantopon, has seemed to be of value in relieving abdominal cramps and frequent purulent bloody discharge in cases of colitis. The evidence obtained experimentally substantiates the antispasmodic effect of papaverine, and it appears to have certain advantages over pantopon in cases where it is desired to immobilize the intestine or put it to rest.

Specific measures for the medical treatment of this disease continue to accumulate. For the most part they have to do with local treatment of the bowel, treatment of various deficiency conditions resulting from the disease and chemotherapeutic measures directed toward more or less control of the factor of bacterial infestation. Gainsborough⁵⁵ treated a group of patients with cod-liver oil retention enemas, and while he frankly states that the method was certainly not a curative one, he believes that it was very efficacious in shortening the illness and reducing pain. He points out that these patients were more tolerant to cod liver oil enemas than to other local applications, a possible point of value in what is obviously merely palliative treatment.

Lerner and Rapaport⁵⁶ assert that vitamin A deficiency is one of the complications of ulcerative colitis, a statement which is not surprising in view of the probable interference of the disease with all fat soluble vitamins. Such a finding indicates, however, that deficiencies secondary to ulcerative colitis are numerous, and illustrates the complexity of the body changes incident to the disease. The suggestion of Cheney⁵⁷ that intensive liver therapy may modify the course of the disease is of some interest, but the evidence

that he presents is unconvincing. There is little doubt that satisfactory remissions accompanied the administration of liver extract, but one must remember that similar remissions occur spontaneously and frequently in this disease. It may well be that liver therapy does improve the patient's general condition to a high degree, but it is doubtful that anything further than this is accomplished.

Although no single chemotherapeutic measure has as yet been evolved that controls the relapses in this condition, sulfanilamide, Neoprontal and other drugs have been mentioned by various writers. One of the most recent reports is that of Hebb, Sullivan and Felton,⁵⁸ who discuss the results obtained in the treatment of 14 cases with rectal lesions of lymphopathia venereum and 4 cases of chronic ulcerative colitis with sodium sulfanilyl sulfanilate or with sodium sulfanilate. That the series is altogether too small to warrant definite conclusions is obvious and is admitted by the authors. The improvement observed in both groups, however is of interest, and in considering the patients with ulcerative colitis, one cannot help but hope that some such measure may control, at least to some degree, what obviously is frequently a bacterial infection of a badly damaged bowel. Any such help would be a welcome addition to our therapeutic measures in controlling the violent and dangerous exacerbations of the disease.

The surgery of the condition has been reviewed by various authors, and it is generally accepted that with the proper indications, an ileostomy, with or without a colectomy, is the best available method at present. The report by Cave,⁵⁹ while not presenting any new material, is of interest to this respect.

MASSACHUSETTS GENERAL HOSPITALANTENATORUM AND POSTANTENATORUM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26151

PRESENTATION OF CASE

A thirty-eight year-old housewife was admitted to the hospital complaining of excruciating abdominal pain, with vomiting of five hours duration.

On retiring at midnight after a somewhat lively family birthday celebration the patient was aware of epigastric discomfort. Considering the party this was interpreted as the result of natural causes and she went to sleep. She awoke, however, about 3:30 a.m. with an intense upper abdominal pain, and began to vomit repeatedly. The pain was constant and unrelenting and felt like a "hot lead pipe the length of the abdomen." It radiated to the back and gradually extended downward. There were no cramps or periumbilical pains. The patient writhed and tossed in the bed and refused to call a physician, at 5:30 a.m. the husband finally called one. The doctor examined her thirty minutes later and found a "silent" abdomen which was somewhat rigid, especially in its upper portions, he also observed flecks of bright and changed blood in the vomitus. She was immediately referred to the hospital.

The patient had been married eighteen months but had not been pregnant. Six months before admission she was told that she had a "fibroid." Several years before entry she had had an appendectomy in an outside hospital.

Physical examination at 8:00 a.m., or about five hours after the onset of the acute pain, revealed a well-developed and well-nourished woman who did not appear very sick. Examination of the heart and lungs was negative. There was no audible peristalsis, and the abdomen was neither distended nor showed areas of definite tenderness. Both rectus muscles were held tight while the sides of the abdomen were soft. Pelvic examination revealed the presence of a tense, tender, cystic mass occupying and filling the posterior cul de sac; the patient identified this mass as the source of her pain. The remainder of the examination was negative.

The temperature was 98°F., the pulse 85, and the respirations 20.

Examination of the blood showed a white-cell count of 10,800, and that of the urine was negative.

Plain roentgen films of the abdomen taken in

the supine, upright and laterosupine positions showed no definitely abnormal loops of small bowel. In the upright position there was a fluid level to the right of the spine in the region of the gall bladder. Since the patient had had an enema before the film was taken, it was thought that this fluid level could have been in the colon instead of the small bowel. There was a small quantity of gas in a nondilated loop of small bowel at the level of the fourth lumbar vertebra. The soft tissues in the pelvis were dense, and there appeared to be a rounded smooth mass in the region of the uterus. There was no air under the diaphragm.

After catheterization the pelvic findings were unchanged. She was taken to the operating room, and an exploratory laparotomy was immediately performed.

DIFFERENTIAL DIAGNOSIS

DR. ARTHUR W. ALLEN: May we see the x-ray films?

DR. FELIX FLEISCHNER: The diaphragms are somewhat high, but there is no free gas below either leaf. I can see the fluid level mentioned. The amount of gas in the bowel appears to be about normal. However there is an area in the lower abdomen and pelvis which fails to show any gas-filled intestinal loop. This coincides with the soft tissue mass which was described. We can rule out perforation of a viscus.

DR. ALLEN: Would you say that the elevation of the diaphragm would give any information about the intra-abdominal pressure?

DR. FLEISCHNER: No. I cannot even state that the position of the diaphragm is unusually high.

DR. ALLEN: We have a young woman with a previously diagnosed pelvic mass, thought to be a fibroid with a sudden attack of abdominal pain. The pain was very excruciating, coming on suddenly and radiating to the back without any cramps and with a normal temperature and pulse and a slightly elevated white count five hours after onset. The x-ray films showed a soft tissue mass in the region of the pelvis. The pelvic examination before operation described a tender cystic mass in the pelvis. All these findings lead up to a perfectly classical textbook story of ovarian cyst with a twisted pedicle. Twists of the ovary and fallopian tube of pedunculated fibroids and so forth are apt to be sudden in onset and to come on while the patient is straining at stool. Such patients do not have any rise in temperature until gangrene develops in the obstructed organ and an elevated white-cell count is the first laboratory evidence that there is something serious about the matter. It is usually around 11,000 at the end of five hours, and it gradually rises.

There are certain factors about this case that

make me slightly suspicious that this obvious diagnosis is not correct. In the first place we are not sure what she means by "pain radiating to the back." If the patient had a penetrating ulcer of the posterior wall of the stomach or duodenum into the pancreas, the pain should radiate directly through the back at that level. If the diseased organ is the gall bladder and the pain radiates to the back the pain may be immediately behind the gall bladder but is more apt to be in the subscapular region. In a patient with small-bowel obstruction one of the chief complaints is backache that is usually in the lumbar region. If the patient has a pelvic disorder with backache, the pain is still lower,—down over the sacrum,—and that holds also for low large-bowel tumors, such as tumors of the sigmoid and rectum. We are only told that this pain radiated to the back.

One of the important observations is the fact that the vomitus was flecked with blood, but I think it probably has no significance because this patient obviously vomited very hard and the flecks of blood probably came from the engorged mucosa, either of the pharynx or esophagus. I believe that the physician who saw her first might have thought that the "silent," tense abdomen, the sudden onset of pain and the liquid indiscretions of the preceding evening might all have contributed to a perforated peptic ulcer. I think it is quite likely that was the provisional diagnosis when she came in here. The physical signs on admission seem to have ruled that out, and I believe the x-ray department believes that air will be found under the diaphragm in 80 to 90 per cent of cases with perforation of a hollow viscus, none was found here. The previous history of indigestion does not mean anything because a silent ulcer may perforate and bleed. I think we can rule out this possibility and that of any disease in the upper abdomen reasonably well.

There is one important part of the history that we must pay very strict attention to and not forget for a moment, that is, the fact that she had had an appendectomy a few years before. One of the common causes of subacute abdominal pain is intestinal obstruction on the basis of adhesions, it may or may not be preceded by a previous operation, but is more apt to come about if an operation has been performed.

Could this be a case of small-bowel obstruction? The onset of the pain was consistent with such a diagnosis, but I should expect the pain to have been described as crampy and not constant, and it states very definitely that there were no cramps or periumbilical pain. The fact that there was a cystic mass in the pelvis does not rule out intestinal obstruction, because we have frequently found during phases of ileus or obstruction a di-

lated loop of small intestine actually filling the pelvis and feeling like a cyst on pelvic examination. Frequently such obstructed loops of bowel have been mistaken for abscesses in the pelvis. The odds about trying to tie this up with small bowel obstruction are quite numerous. The character of the pain was wrong. We note the radiation of pain, but not to the right portion of the back. The fact that her abdomen was "silent" at the time the physician first listened to it before she had medication and again when she came in here is also against it. Also, I think it is unusual in intestinal obstruction not to have more evidence of dilated loops by x-ray even at the end of five hours, and I should not expect such a clear-cut round shadow as we have in this case.

I think one has to come down to an acute abdominal condition on the basis of a pelvic mass that has not gone far enough in its process to produce fever or much change in pulse or respiration, and only a slight elevation in white-cell count. I have to come back to my first impression, namely an ovarian cyst with a twisted pedicle.

DR WALTER BAUER Might it not have been an acute gastritis and an ovarian cyst which was not twisted?

DR ALLEN I think that is quite possible. I should hardly expect the pain to persist after she stopped vomiting and to be associated with this other mass which was felt by pelvic examination.

DR HORATIO ROGERS Dr Richardson saw this patient first, and I saw her when she came into the hospital. At first, as Dr Allen discussed it, I thought he must be familiar with the case because he followed exactly our line of reasoning. Dr Richardson at first thought it was probably an ulcer which had perforated into the lesser peritoneal cavity, and after we had the patient in the hospital and had more data my diagnosis was twisted ovarian cyst. It was on that diagnosis that I operated and found 50 cm of gangrenous small intestine in the pelvis, free bloody fluid and a tight band of omentum adherent to the site of the appendectomy under which the intestine had gone. It was quite easy to put my finger under this band, lift it up and cut it, whereupon the gangrenous intestine came up into the wound. We could then see the constrictions where the bowel and the mesentery had been dragged through under the band. We watched the intestine a reasonable length of time for the return of color, but as it stayed black it was resected. The patient made an uneventful recovery and went home on the sixteenth postoperative day.

DR TRACY B MALLORY Have you anything to add, Dr Richardson?

DR WYMAN RICHARDSON My diagnosis was

ruptured gastric ulcer. When I heard about the pelvic examination I said "I did not do it. Perhaps there was pus down there in the pelvis." The first striking thing about this patient was the subnormal temperature, furthermore, she seemed to be in good condition in spite of the most terrific pain. Another interesting feature was that the pain at six o'clock in the morning was high above the umbilicus in the epigastrium, radiating straight through to the back, it was very severe and non-cramplike. Later it began to radiate down in a vertical line, never radiating horizontally across the back. In retrospect I think probably the last is an important clinical finding to emphasize.

Dr. MALLORY: Did you find a fibroid?

Dr. ROGERS: Yes, there was an 8-cm fibroid which had nothing to do with the picture.

Dr. BAUER: Do you think that what you felt was the loop of small bowel?

Dr. ROGERS: I am certain of it. It was impressive how accurately the patient could tell when I touched it. It is of interest that when I reviewed the patient's history with her a few days later I still could not elicit a story that sounded at all like that of intestinal obstruction.

Dr. BAUER: If you were asked to feel a pelvis like this again, would you be able to say "This is small bowel and not a cyst?"

Dr. ROGERS: No, I think I should make the same mistake again.

Dr. GEORGE W. HOLMES: How long before the operation was the x-ray taken?

Dr. ROGERS: About five and a half hours.

Dr. HOLMES: The absence of dilated loops in the bowel is difficult to explain. Have you any explanation?

Dr. ROGERS: She apparently did not have time to develop gaseous distention. The loops of bowel in the pelvis were not distended with gas but with fluid.

CLINICAL DIAGNOSIS

Twisted ovarian cyst, with strangulation and gangrene.

Dr. ALLEN'S DIAGNOSIS

Twisted ovarian cyst

ANATOMICAL DIAGNOSIS

Gangrene of small bowel secondary to strangulation by adhesive band

PATHOLOGICAL DISCUSSION

Dr. MALLORY: The specimen we received showed gangrene of the bowel, but we were disturbed by the fact that there was no thrombosis either in the arteries or in the veins. Evidently the strangu-

lation by the adhesive band was so complete that the blood supply was totally cut off.

Dr. GRANTLEY W. TAYLOR: Have you any knowledge at what level of small intestine the obstruction occurred?

Dr. ROGERS: About 50 cm above the cecum.

CASE 26152

PRESENTATION OF CASE

An eleven-year-old American schoolboy entered the hospital with the complaint of jaundice of thirteen days' duration.

He had been perfectly well until thirteen days before entry when his schoolmates told him that his eyes were yellow. He had no complaints at that time except slight anorexia, although his urine was dark colored and his stools were somewhat paler than normal. He had no fever, vomiting, diarrhea or definite malaise, but occasionally did feel slightly nauseated. He stayed in bed for three days and at home for a total of a week. He returned to school for three days, after which his vacation began. His condition remained unchanged until two days before entry when it was noticed that his abdomen was enlarging. He began to complain that he had some abdominal pain when he bent over and that he felt somewhat listless. At no time had he had any fever, and the appearance of his jaundice was not preceded by any event which he could remember, such as the eating of a heavy meal. During the evening before entry he had severe pain in his rectum while moving his bowels. He had had no other symptoms.

The past history and family history were essentially negative. He had had measles, whooping cough, mumps and chicken pox. Before entering school his tonsils and adenoids had been removed because of occasional sore throats. He had had two or three colds a year but never any previous jaundice or prolonged periods of malaise. None of his schoolmates and no other members of his family were ever known to have had jaundice.

Physical examination revealed a well-developed and well-nourished boy in no apparent discomfort. The skin and sclerae were light yellow in color. The heart and lungs were negative. The blood pressure was 120 systolic, 80 diastolic. The abdomen was very protuberant, and the umbilicus bulged. The percussion note was tympanic in the midline and dull in the flanks. There was shifting dullness, but a definite fluid wave could not be made out. There was questionable tenderness, but no spasm. The liver could be palpated about 3 cm below the costal margin. Its edge was moderately firm, slightly tender, sharp and definitely

uneven The left lobe of the liver could not be palpated, but there was a mass in the left upper quadrant extending about 3 cm below the costal margin, which seemed to move on respiration. The extremities were negative.

The temperature was 99.5°F, the pulse 80, and the respirations 20.

The urine examination was negative. The blood showed a red-cell count of 3,400,000 with 70 per cent hemoglobin, and a white-cell count of 5600 with 62 per cent polymorphonuclears. The stools were brown in color and gave a ++ test for bile. The whole-blood nonprotein nitrogen was 28 mg per 100 cc, the serum protein 7 gm, with an albumin-globulin ratio of 1.0, the van den Bergh 134 mg biphasic, the phosphorus 2.90 mg, and the total cholesterol 135 mg. The chlorides were equivalent to 114 cc of N/10 sodium chloride. A sugar-tolerance test showed a fasting level of 54 mg per 100 cc, 109 mg at a half hour, 160 mg at one and a half hours, and 80 mg at three hours. The blood Hinton test was negative, as was a 1:1000 tuberculin test. An x-ray of the abdomen showed an enlarged liver and spleen. There were no unusual areas of calcification, and the kidneys were normal in size, shape and position. There was no evidence of disease in the bones of the arm or in those around the knee joints, and a skull plate was negative. An x-ray of the esophagus showed it to be slightly dilated. The rugae of the lower half were tortuous, definitely indicating the presence of varices.

For the first month in the hospital the temperature rose daily to 100°F, falling to normal during the night. Several urine examinations were normal, and the stools continued to contain bile. The red-cell count remained at a level of about 3,500,000, but he showed a persistent leukopenia, the white-cell count falling as low as 3250 with 65 per cent polymorphonuclears. During the first ten days the jaundice practically disappeared, but the ascites persisted. His condition otherwise remained unchanged.

An x-ray film of the chest taken at the end of the first month showed excellent excursion of the heart, with no calcification in the pericardium, no widening of the superior mediastinum and no evidence of adhesive pericarditis. On the thirty-seventh day an omentopexy was performed, following which he developed an acute otitis media which drained spontaneously. A culture of the pus yielded hemolytic streptococci. For seven days after the operation he had a septic temperature rising daily to 102°F., and he developed signs of consolidation in the chest. An x-ray film showed hazy dullness in the middle third of the right lung and at the left base. However, the otitis media and apparent pneumonia cleared up completely in a few days.

His course was uneventful for the next three weeks but at that time, nine weeks after entry, he began to have greater elevations of temperature, with a daily rise to 101 or 103°F. By that time the red-cell count had fallen to 2,800,000, with 56 per cent hemoglobin, and the white-cell count was 4600, with 38 per cent polymorphonuclears, 54 per cent lymphocytes and 8 per cent monocytes. A repeat x-ray plate of the esophagus showed varices more clearly visible and wider than at the first examination. A bromsulfalein test of liver function showed 40 per cent retention after five minutes, and 20 per cent after thirty minutes. The serum protein was 6.5 gm per 100 cc., the van den Bergh 341 mg, and the nonprotein nitrogen 23 mg. During the tenth week he again developed jaundice, which disappeared in the next ten days. The ascites increased in amount, and he had some diarrhea.

More careful inquiry into the patient's family history revealed syphilis in the mother and older sister. The mother had had positive serological tests one year before the patient's birth and had had three or four treatments at that time. On the basis of this, antisyphilitic therapy was begun, with potassium iodide and mercury by mouth. A lumbar puncture showed normal findings, with a negative Wassermann test on the spinal fluid. An abdominal paracentesis was done at the end of the twelfth week, and 4000 cc of clear straw-colored fluid was removed. A Wassermann test on the fluid was moderately positive. In the meantime the temperature fluctuation had become less marked, rising only to 100°F daily. Two cubic centimeters of Mercupurin intravenously produced 4500 cc of urine in the following twelve hours, two more abdominal paracenteses were done, yielding a total of 12,300 cc of straw-colored fluid. In the middle of the fourteenth week the urine for the first time showed a trace of albumin and contained occasional casts. Two subsequent specimens showed similar findings, and one contained 5 to 10 red cells per high-power field.

On the second day of the sixteenth week he suddenly vomited about 500 cc of coffee grounds material streaked with red blood. He became very restless and somewhat delirious and cried out as if in pain. There was a definite uremic odor to the breath. The nonprotein nitrogen of the blood serum was 55 mg per 100 cc., and the serum protein 5.5 gm. He was given 1/8 gr of morphine subcutaneously for the restlessness, and soon lapsed into coma with Cheyne-Stokes respirations. He remained in coma until his death, thirty-six hours later.

DIFFERENTIAL DIAGNOSIS

DR. JOHN H. TALBOTT The first diagnosis which

enters my mind when mention is made of an eleven year-old jaundiced schoolboy is catarrhal jaundice. As we read through the history, however, it is obvious that the diagnosis is not so easy as this. I should like to stress the point that he felt perfectly well until shortly before admission. The negative family history helps us to exclude certain familial maladies, such as hemolytic jaundice, Gaucher's disease and Cooley's anemia. On physical examination he was well developed and well nourished but had a prominent abdomen and a bulging umbilicus. Dullness in the flanks and the tympanic percussion note in the midline confirm the impression that there was an increased amount of abdominal fluid. It is possible for a huge spleen, such as may be found in myelogenous leukemia or Gaucher's disease, to simulate ascites, but any such degree of splenomegaly evidently was not present. The only mention that is made of a palpable spleen is the statement that a mass was felt in the left upper quadrant which descended on respiration. Until proved otherwise I shall consider this to be a spleen.

The enlargement of the liver, anemia and leukopenia are the first data which suggest that the malady from which this patient suffered was more chronic than the history admits. The anemia was associated with a color index that was slightly above normal, a fact which indicates that the former was not caused by chronic blood loss. The presence of bile in the urine together with a brown colored stool is in favor of intrahepatic rather than obstructive jaundice. The concentration of serum protein was normal, namely 7 gm per 100 cc. However, the albumin-globulin ratio was decreased, undoubtedly due to an increased concentration of serum globulin at the expense of serum albumin. The concentration of cholesterol was 135 mg per 100 cc. Similar low normal values may be found in patients with an acute hepatitis. The serum chlorides were considerably above normal. I recall one patient suffering from an idiopathic cirrhosis of the liver and bleeding esophageal varices who had a concentration of serum chlorides even greater than this. I do not know the significance of this association. The sugar tolerance curve is consistent with intrahepatic disease. The x-ray studies of the esophagus showed varices in the lower portion. The x-rays of the long bones and skull were taken presumably to help exclude xanthomatosis and Gaucher's disease. During his stay in the hospital further x-rays were taken to detect any calcification of the pericardium. From the data given in this abstract, I doubt very much whether I should have thought seriously of constrictive pericarditis to explain the whole picture.

An omentopexy was performed during the sixth hospital week. I should have been pleased to have a statement from the surgeon concerning the texture of the splenic and portal veins as well as that of the spleen. Following operation he contracted an acute otitis media and, later, patchy consolidation of the lungs, possibly a transient streptococcal pneumonia. Daily elevation of temperature suggests lymphoma or Hodgkin's disease, but there is little else to corroborate this impression. It is true that there was a relative increase in lymphocytes, but I should certainly not make a diagnosis of lymphoblastoma on this one report. The 20 per cent retention of bromsulfalein after thirty minutes is consistent with moderate impairment of liver function.

The family history of syphilis was discovered rather late in the disease to be of much help to the patient or to us in our differential diagnosis. On admission the blood Hinton reaction was negative, and the spinal-fluid Wassermann test subsequently negative. A moderately positive ascitic fluid Wassermann test only confuses me. If this patient were suffering from congenital syphilis of the liver and spleen, I should expect other stigmas and positive serum reactions.

Albumin and casts were noted in the urine shortly before death. These may be part of what is called the hepatorenal syndrome, about which, I confess, I have only a very hazy mental picture. The exitus was a rather precipitous one. The patient had a massive hemorrhage and vomited old and new blood. The restlessness following this hemorrhage or hemorrhages was treated with morphine. Apparently whoever ordered this drug failed to heed the advice of Dr. Mallory that morphine, even in small doses, is harmful to patients with cirrhosis of the liver. I should think that his death was incited by the hemorrhage and hastened by the morphine.

I believe that this boy was suffering from cirrhosis of the liver, splenomegaly, and thrombophlebitis of the splenic vein with esophageal varices. The cirrhosis may well have been idiopathic, but the whole picture fits the syndrome described by Banti. The occurrence of varices in syphilis of the liver is unusual. I should hesitate to call this congenital syphilis without additional evidence. It seems that the death might have been premature and that if he had survived the first hemorrhage he might have lived for several years.

DR. GEORGE W. HOLMES. The first film shows the characteristic picture of esophageal varices, namely the worm-like shadows of diminished density. In the second film the esophagus looks normal. That frequently happens in cases with

varices, and is a fairly good way to distinguish between deformity of the esophagus due to varices and that due to tumor. In the plain film taken of the abdomen, the edge of the liver is about 2.5 cm above the crest of the ilium, and there is a large area of increased density in the left upper quadrant, which might be a very much enlarged spleen. There is mottled dullness in the upper part of the right lung field, with similar shadows in the lower part. The bones of the skull, wrists and knees are negative.

A PHYSICIAN I should like to ask if morphine would be considered adequate cause of the terminal coma. At that age $\frac{1}{8}$ gr might be enough to cause it.

DR TRACY B MALLORY I have been impressed that following a single dose of morphine it is not uncommon for a patient with cirrhosis to develop coma and never come out of it. However, in view of the autopsy findings in this case it would be rash to conclude the morphine was solely responsible.

Dr Higgins, do you remember Dr Beth Vincent's findings at the time of operation?

DR HAROLD L HIGGINS The liver felt rough and was not nearly so large as had been thought on clinical examination. Because the patient had jaundice he thought preoperatively that the primary disease was in the liver and expected to find cirrhosis.

CLINICAL DIAGNOSIS

Cirrhosis of the liver ("toxic type" on biopsy)

DR. TALBOTT'S DIAGNOSES

Cirrhosis of the liver, splenomegaly, and thrombophlebitis of the splenic vein
Banti's syndrome?
Morphine intoxication

ANATOMICAL DIAGNOSES

Cirrhosis of liver, toxic
Septicemia, *Streptococcus haemolyticus*
Fibrosis of spleen
Otitis media, acute purulent
Ascites
Pleural effusion
Pulmonary congestion, slight
Acute glomerular nephritis, terminal
Operative wound omentopexy

PATHOLOGICAL DISCUSSION

DR MALLORY At the time of autopsy we found a slightly small liver, weighing 800 or 900 gm. It was very nodular and cirrhotic, and the nodules varied from a millimeter to a centimeter in size. On microscopic examination the liver architecture was totally destroyed. The liver cells were grouped

in clusters of varying size, without orientation about any central vein to differentiate lobular formation. Between the clusters of liver cells were bands of fibrous tissue containing innumerable bile ducts, which in some areas showed extensive branching, a picture which suggests that multiple contiguous liver lobules had been completely destroyed. In other words, the architecture was essentially that of a healed or nearly healed acute atrophy, with consequent early cirrhosis. There was still some progressive necrosis of the liver cells. The spleen was considerably enlarged, weighing 450 gm, and it showed very early fibrotic changes of the type one finds with any form of portal obstruction. There were no thrombi in the splenic or portal veins.

Microscopic examination provided one surprise. The kidneys showed a very early but definite glomerulonephritis, which I should tie up with a terminal streptococcal sepsis. The blood culture at the time of autopsy showed a beta hemolytic streptococcus.

I should not, personally, regard this case as an example of the currently much debated hepatorenal syndrome. In the few reliably reported necropsies dealing with this disease the lesion has been tubular rather than glomerular.

If I may step out of my role and discuss the differential diagnosis I am sorry that Dr Talbott did not consider the Banti's syndrome a little more fully. The hematemeses, the esophageal varices, the splenomegaly, the anemia and the persistent leukopenia clearly place this patient in that category, and experience tells us that such patients always have obstruction in the portal system or in the splenic veins. In adults the former is far commoner and is usually the result of cirrhosis of the liver. In children, however, portal and splenic vein thrombosis without cirrhosis occurs with significant frequency and must be given serious consideration. The presence of jaundice was, in this case, strong prima facie evidence in favor of cirrhosis. Had jaundice been lacking, the presence of ascites and the reversed albumin globulin ratio would have become important. Portal obstruction alone rarely produces ascites unless the serum albumin is lowered, and lowering of the serum albumin is strongly suggestive of hepatic insufficiency.

DR TALBOTT There was no evidence of syphilis?

DR MALLORY No.

A PHYSICIAN Have you any explanation for the intermittent character of the jaundice?

DR MALLORY No, but I am sure we have seen fluctuations in the level of hepatic incompetence in other cases of cirrhosis.

ULTRA VIOLET CURTAINS

The Wellset¹ have conclusively proved that where an aqueous suspension of pathogenic bacteria is thrown into the air by an atomizer the water immediately evaporates and the micro-organisms remain suspended and animate in the air for hours and even days. On the basis of their observations they have advanced the ideas that contaminated air is responsible for the majority of nasopharyngeal infections and that the purification of air by means of ultra violet radiation is an important factor in the control of such diseases, particularly in hospitals, nurseries and the like. Furthermore, a speaker² at the last meeting of the American Public Health Association even expressed the belief that influenza and other respiratory diseases could be controlled by means of a curtain of ultra violet rays. Of these three

thoughts, the first appears to be obvious, the second, probable, and the third, fantastic.

Granting that such rays are effective bactericidal and viricidal agents and are excellent for the sterilization of contaminated inanimate objects, such as plates and tumblers, how can they be applied to the infected individual, be he carrier or patient? Again, acknowledging that the bacterium or virus cannot pass through an ultra violet curtain, how can such curtains be employed to protect a healthy populace? To consider an individual curtain drawn about each carrier or patient is an absurdity. A more pretentious one to protect a nursery full of children or a barrack of soldiers might work if one could be sure that those to be protected never left their haven and that no one from the outside ever entered both of which are obvious impossibilities. A wall of flame would seem to be just as practical and much more effective.

Attempts along similar lines to prevent sepsis following "clean" operations seem equally futile, for it is a well known fact that by far the majority of infections following this type of operation are due to micro-organisms from the mouth nose or throat of the operator or one of his assistants, rather than to those which are circulating in the air of the operating room. The operative field cannot be exposed to ultra violet rays, because tissue cells also succumb to such radiation. It is conceivable that a horizontal curtain of rays, just above the operating field, might have some effect, but many of the rays would be blocked by hands and instruments.

Until some agent is discovered which is more toxic for bacteria and viruses than it is for other living cells,—including those making up the human body,—epidemics due to diseases of the upper respiratory tract can be controlled only by the strict quarantine of patients, by the elimination of carriers and by measures to increase the specific or non specific resistance of the populace. Furthermore, it seems likely that unexplained post operative sepsis can best be prevented by the use of effective masks—if such there be—and by the elimination from the operating team of all those who harbor hemolytic streptococci in their mouths, noses or throats.

AMERICAN SOCIAL HYGIENE ASSOCIATION

THE far-reaching program of the American Social Hygiene Association is not fully realized until one is confronted by the evidence of its activity. A recent pamphlet issued* by this association shows that taking the population as a whole one person in every twenty is infected with syphilis. This figure is not an exaggeration, and assumes even greater significance if one realizes that the incidence of syphilis is 50 per cent greater than that of tuberculosis, and that there are twenty-eight times as many individuals attacked by syphilis as by infantile paralysis.

The association has performed valiant service in furnishing information about syphilis and gonorrhea to the public. By exhibits, by lectures, by material furnished to newspapers and magazines, by radio, by mail and by moving picture films, wide publicity concerning these diseases has been given to millions of people. The staff members have traveled widely in order to increase contacts with clubs and societies and to set up local social-hygiene groups. The association has been influential in the establishment of premarital and prenatal examinations. Its legal staff has encouraged efficient administration of existing control laws, has made prostitution surveys in many cities and states and has studied medical quackery, particularly with regard to syphilis and gonorrhea, in forty-four cities in twenty-five states. It has furthermore made special studies of conditions near Army and Navy recruiting and training stations.

Its public-health and technical medical consultants have been continuously available to physicians and medical institutions. It has continued its program on sex education and has joined with the United States Public Health Service in the evaluation of health education in schools and colleges.

*How Social Hygiene Reached Out to Millions in 1939 New York American Social Hygiene Association 1940

While encouraged and endorsed by state and federal public-health agencies, all these activities have been supported and made possible by public subscription. Publication of facts and education are half the battle, and it is to be hoped that the funds will be forthcoming to continue this well-organized attack on the problem of genito-infectious diseases. Benefits are accruing, and will still further appear in the form of a decreased incidence of these diseases and fewer serious complications of such infections. This country is indeed fortunate in having an influential, vigorous association conducting such an aggressive campaign against these menaces to public health.

MEDICAL EPONYM

BORDET-GENGOU BACILLUS

The etiologic agent of whooping cough was described by Jules Bordet and Octave Gengou, of Brussels, in an article entitled "Le microbe de la coqueluche [The microbe of whooping cough]" in the *Annales de l'Institut Pasteur* (20 731-741, 1906). The translation of a portion of the article follows.

We have been able during the past year to isolate the specific microbe. The authenticity of this microbe as the causal agent of whooping cough depends, to be sure, in large part on the circumstances which existed when it was obtained, but the chief argument seemed to us to be furnished by the study of the specific properties of the serum. The serums of individuals who have not had whooping cough or who had it a considerable time previously, even in large amounts, do not agglutinate the microbe. The serums of children recently recovered from this illness possess an agglutinating power which is of moderate degree, but constant and definite.

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TITUS, M.D., Secretary
330 Dartmouth Street
Boston

SEPSIS FOLLOWING CESAREAN SECTION

Mrs. P, a thirty-one-year-old primipara at term, started in labor on March 30, 1927. Because of a high fetal head, she was seen in consultation

*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

The family history was non-contributory. The past history included diphtheria at the age of three and mastoiditis at fourteen, for which no operation was performed. The tonsils had been removed. There was a history of "heart trouble" after an attack of influenza. Catamenia began at fourteen, were regular with a twenty-eight-day cycle and lasted four days without discomfort. The last period was June 16, 1926, making the expected date of confinement March 23.

The pregnancy had been complicated by Epstein's nephrosis. The urine had contained very large traces of albumin almost all the time, and the blood pressure had ranged from 118 to 130 systolic, 60 to 80 diastolic. She had a large amount of edema and gained 45 pounds in weight. The highest blood pressure recorded was 130 systolic, 60 diastolic, the day before delivery.

Cesarean section was advised. This was done under nitrous oxide, oxygen and ether anesthesia, and an 11 pound, 1 ounce, baby was delivered in good condition.

The day following operation, March 31, the temperature was 99.4°F, with a pulse of 92, and she complained of pain in the right shoulder blade. The temperature rose until it reached 105.6°F on April 2, with a pulse of 140 and respirations of 48. A medical consultation was held, and an x-ray showed pneumonia in both lungs. The temperature came down to normal on April 6, and vacillated between 98 and 99.6°F from then until April 15. On April 15 the temperature rose to 101.4°F, and the pulse to 120. At this time there was very definite tenderness throughout the lower abdomen. From April 16 to April 25 the temperature ranged from 99 to 101°F, but it came down to normal on April 25. From April 26 to May 21 the temperature ranged from 98 to 101°F, with a pulse of 90 to 110. During this period the tenderness in the lower abdomen subsided but a definite mass appeared in the epigastrium.

On June 7, because the temperature was still vacillating between 98 and 101°F and definite induration was felt below the umbilicus on the left, an exploratory laparotomy was undertaken. By this time the mass in the epigastrium had entirely disappeared, and exploration was carried out through an incision to the left of the midline about at the level of the anterior superior spine. No pus was obtained. From the time of operation until June 21 the temperature ranged from 100 to 102°F. From June 22 to June 30 it ranged from 98 to 99.2°F. There was one acute exacerbation on July 6 to 104°F, without anything being found on physical examination. From July 11 until discharge on July 22 the temperature re-

mained normal. During the period from April 15 until ten days before discharge there was a large amount of thin, foul discharge from the vagina, this definitely came from the uterus.

The white-cell counts during this period ranged from 15,000 to 20,000. The urine, save for a large amount of albumin, was always negative. No cultures were taken.

Comment. This case of sepsis following cesarean section began with double pneumonia, a very common complication of Epstein's nephrosis. Whether the infection in the uterus was a blood stream infection following the pneumonia is debatable. No uterine or blood cultures were taken. It is quite likely that at one time or another there was an abscess in the uterine wall which broke into the peritoneal cavity, was walled off and resulted in the definite mass that was felt in the epigastrium. Surgical interference had been considered off and on during convalescence, and was undertaken on June 7, with the idea of draining an abscess cavity and thus shortening the convalescence. This was not achieved. At no time was the uterus invaded.

When seen seven weeks after discharge, the patient's weight had increased from 102 to 123 pounds and she looked very well. The upper two thirds of the cesarean scar presented a hernia. Vaginal examination showed an indefinite fullness on the left, which it was believed would ultimately disappear.

This patient died of nephritis about three years later.

COMMITTEE ON INDUSTRIAL HEALTH

The Committee on Industrial Health has made two reports in which it has brought before the members of the Society what is considered as good practice in industrial medicine. These have been written to assist the general practitioner who is giving part of his time to industrial work.

The committee now proposes from time to time to give short reports of industrial cases. It is hoped that members of the Society will send to the committee similar reports for publication in the *Journal*.

The committee will be glad to answer, to the best of its ability, questions on industrial medicine sent to its secretary Dr. Louis R. Daniels, Hood Rubber Company, Watertown.

MODERATE PLUMBISM

F. F., aged 37 years and weight 183 pounds, a battery repairman for 1½ years, reported at the company dispensary on August 10, 1938, complaining of a severe pain in the hypogastric region. He gave a history of some

constipation, moderate loss of weight, weakness and anorexia. Abdominal examination was negative, the pulse and temperature were normal. The outstanding clinical feature was his extreme pallor. There was a suggestive lead line. A tentative diagnosis of plumbism was made. The following day a clinical laboratory reported as follows: "red cell count 4,500,000, hemoglobin, 80 per cent, smear shows an occasional stippled red cell, red cells are normal in size and shape."

The man was sent home with directions to obtain catharsis with salines, to drink a quart of milk daily and to take belladonna for cramps. In a week he reported that he felt well and that he had had no further abdominal distress. On reporting to work the following day, he was assigned to a job with no lead hazard.

Comment A case of moderate plumbism is described which occurred in a battery repairman of 1½ years' service, despite the fact that there had been no cases of plumbism for 50 years among the other men similarly employed. His pallor was all out of proportion to his anemia, it was apparent, and the stippled-cell count alone does not establish the diagnosis of plumbism.

For the past year and a half the score of battery repairmen have been examined each month. About 60 per cent of them showed from 2 to 20 stippled cells in 200 oil-immersion fields. None of them have shown any symptoms of plumbism during the period, except one man who showed a lead line daily during a 2-week period when his stippled-cell count jumped from 7 to 32. He was told to drink a quart of milk daily for a couple of weeks while he continued at his job. His stippled count then returned to the original normal level of 1 to 7. Improved housekeeping methods and forced ventilation during the "burning in" of battery plates should prevent further plumbism in the plant.

Conclusions There is a marked individual susceptibility to plumbism. Extreme pallor with only moderate anemia is indicative of the disease. The mere presence of stippled cells in the blood is not sufficient to make a diagnosis. Workmen exposed to lead who show symptoms of plumbism or a consistently rising stippled-cell curve should be placed where there is no lead hazard.

DERMATITIS VENENATA

On November 24, 1931, J. F. W., a lineman, reported to the company dispensary, exhibiting a skin rash of the hands which had every appearance of an early poison ivy dermatitis. He gave a history of picking up old guy wire in the brush along a roadside.

A dermatologist, employed by the insurance carrier, reported the rash to be industrial in origin and probably caused by lack of skin ventilation due to the constant wearing of gauntlet rubber gloves. He described it as follows: "On the backs of both hands and fingers and encircling the wrists is a dermatitis the lesions of which are red, slightly swollen and very itchy."

On February 1, 1932, a similar case appeared at the dispensary, and the same dermatologist noted that the rash appeared after the man had changed from one color of rubber glove to another. When the sixth similar case arrived on March 1, the man brought his gloves with him and the company physician patch-tested himself with a square of the glove, a markedly red, swollen and itching dermatitis developed under the square in about 16 hours. Patch tests done with other makes of gloves at the same time were negative. Therefore, the make of glove which gave the positive patch tests was eliminated, and no further dermatitis has developed.

Comment This dermatitis was definitely one due to an external irritant, but it took some time to incriminate the gloves, because the make of glove that had caused the dermatitis had been in use for years with no resulting dermatitis. Further investigation revealed that the glove manufacturer had used a new accelerator without previous determination of its irritant qualities. All men who wore the irritant gloves did not develop the rash, however; one man who wore the gloves for only 5 minutes developed a severe rash.

Conclusion There is a marked variance in individual susceptibility to external irritants which may cause a contact dermatitis.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 14.

BERKSHIRE

Thursday, April 18, at 4 30 p.m., at the Bishop House of Mercy Hospital, Pittsfield. Pediatric Institute. Discussion of hospital patients. Instructors: James M. Baty and Elmer W. Barron. Harry G. Mellen, *Chairman*.

BRISTOL SOUTH (Fall River Section)

Tuesday, April 16, at 4 30 p.m., at the Union Hospital, Fall River. Pediatric clinical cases. Instructors: Warren R. Sisson and Lewis W. Hill. Howard P. Sawyer, *Chairman*.

FRANKLIN

Thursday, April 18, at 8 15 p.m., at the Franklin County Hospital, Greenfield. Complications in Obstetrics. Illustrated by case histories. Instructor: Christopher J. Duncan. Halbert G. Stetson, *Chairman*.

HAMPDEN

Thursday, April 18, at 4 00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 15 p.m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Common Laboratory Procedures in Pediatrics and Their Interpretation. Instructor: LeRoy D. Fothergill. George L. Schadt, *Chairman*.

HAMPSHIRE

Thursday, April 18, at 4 15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton. Pneumonia. Instructor: Earle M. Chapman. Warren P. Cordes, *Chairman*.

MIDDLESEX SOUTH

Tuesday, April 16, at 4 30 p.m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Head and Spine Injuries. Instructor: Walter R. Wegner. Dudley Merrill, *Chairman*.

NORFOLK

Thursday, April 18, at 8 30 p.m., at the Norwood Hospital, Norwood. Head and Spine Injuries. Instructor: Donald Munro. Hugo B. C. Riemer, *Chairman*.

NORFOLK SOUTH

Monday April 15, at 8 30 p.m., at the Quincy City Hospital Quincy Pneumonia. Instructor Don ald S. King. David L. Belding, *Chairman*

PLYMOUTH

Tuesday April 16 at 4-00 p.m., in the Nurses Home of the Brockton Hospital, Brockton. Common Problems of Neurology. Indications for lumbar puncture. Instructor T J C. von Storch. Walter H. Pulsifer, *Chairman*

SUFFOLK

Thursday April 18, at 4.30 p.m. in John Ware Hall Boston Medical Library 8 Fenway Boston Gonorrhea in the Female. Instructor Alonzo K. Paue. Reginald Fitz, *Chairman*

ANNUAL PRIZE FOR INTERNS

The attention of interns in Massachusetts hospitals is called to the fact that a prize of \$50.00 has been offered by the Massachusetts Medical Society for the best written and most comprehensive case report submitted by one of their number holding an internship in any Massachusetts hospital which is approved by the American Medical Association for intern training during 1938-1940.

This report is to be typewritten, and when completed is to be sealed, unsigned in a plain envelope, which in turn is to be placed together with a separate slip bearing the name and address of the contestant, in a larger envelope, and sent to Committee on Medical Education and Medical Diplomas, Massachusetts Medical Society 8 Fenway Boston.

The contest this year closes May 5 1940. Reports may be submitted at any time prior to that date.

DEATHS

DERVIN—LAWRENCE J. DERVIN, M.D. of Somerville, died March 30. He was in his sixty-fifth year.

Born in Clinton, he graduated from Fordham University and received his degree from Ludwig Maximilians-Universität Medizinische Fakultät in Munich, Germany. Dr. Dervin had practiced medicine in Somerville for thirty-five years. From 1926 to 1930 he was teaching assistant in pediatrics at Tufts College Medical School. Dr. Dervin was a member of the Massachusetts Medical Society, the American Medical Association and the New England Pediatric Society.

His widow two sons, two daughters and two sisters survive him.

FELCH—LEWIS P. FELCH, M.D., of Boston died April 2. He was in his sixty-ninth year.

Born in Nashua New Hampshire, he graduated from the Massachusetts College of Pharmacy and received his degree from Tufts College Medical School in 1906. He was appointed house officer at the Massachusetts General Hospital in 1909 and was appointed to the staff in 1912, resigning in 1922. He had been medical examiner for the industrial accident board for the past twenty-two years. Dr. Felch was a fellow of the Massachusetts Medical Society and the American Medical Association and held membership in the Boston Orthopedic Club.

His widow Dr. Carrie Innes Felch, who was in his class at Tufts, survives him.

HILTPOLD—WERNER HILTPOLD, M.D., of Easthampton, died April 5. He was in his fifty-second year.

Dr. Hiltbold received his degree in 1912 from the University of Vermont College of Medicine. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

MAINS—HERBERT L. MAINS, M.D., of Danvers, died April 7. He was in his sixty-fourth year.

Born in Salem New Hampshire, his family moved to Danvers where he attended school. He graduated from Dean Academy and received his degree from the University of Vermont College of Medicine in 1912. He served his internship at Western Hospital in Montreal Canada and entered private practice in Danvers. Later he became associated with the United States Veterans Bureau in Boston and then with various hospitals for tuberculosis and mental patients in New York. He returned to private practice in Danvers in 1936.

Dr. Mains was a member of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

MORSE—JOHN L. MORSE, M.D. of Newton, died April 3. He was in his seventy-sixth year.

Born in Taunton he attended Harvard University and received his degree from Harvard Medical School in 1891. He served his internship at the Boston City Hospital from 1890 to 1892. Later he served as an assistant in the Department for Diseases of the Nervous System at the Boston Dispensary and did orthopedic work at the Children's Hospital. He was also house physician at the Boston Lying in Hospital and was registrar of the Carney Hospital and district physician at the Boston Dispensary. For a number of years he served as chief of the medical staffs of the Children's and Infants' hospitals. At the time of his death he was consulting physician at the Children's Hospital, Infants' Hospital, Boston Floating Hospital, Beth Israel Hospital and the North Shore Babies Hospital.

In 1896 Dr. Morse joined the faculty of the Harvard Medical School as assistant in clinical medicine, and four years later became instructor in clinical medicine. In 1903 he was appointed instructor in pediatrics, in 1906 assistant professor of pediatrics and in 1911 associate professor of pediatrics. In 1915 he became professor and served until 1921 when he became professor emeritus.

Dr. Morse was a fellow of the Massachusetts Medical Society and the American Medical Association. He was twice president of the New England Pediatric Society and the American Pediatric Society and was a co-founder of the American Academy of Pediatrics.

His widow a son and three grandchildren survive him.

MISCELLANY

MEDICAL STORES BOUGHT BY RED CROSS FOR WAR RELIEF

Medicines hospital and surgical supplies loom large in American Red Cross war relief purchases, according to a recent tabulation of articles which that organization is furnishing its sister societies in war-affected countries to assist them in minimizing the sufferings consequent to hostilities.

Analysis of the tabulation dated April 1 reveals the following purchases: 500,000 tablets of sulfanilamide, 266,000 tablets of sulfapyridine, 100 tons of other assorted drugs, 23,000 surgical instruments, 38 x-ray units, 32 gen-

erating motors for x ray units, a 100-bed hospital unit, containing 700 items, 25 hospital tents each of 50-patient capacity, 11 motor ambulances, 1,500,000 yards of surgical gauze, 92,000 pounds of absorbent cotton for medical purposes, 276,000 yards of bed sheeting and large quantities of soap toothbrushes and other similar products

Purchases for relief also included 120,000 blankets, 105,000 suits of knitted underwear, 45,000 pairs of shoes and various other articles of clothing. In addition, women volunteers in Red Cross chapters all over the country have produced 344,000 garments and 500,000 surgical dressings. These are sent to the Red Cross warehouse in New York, where they are packed and shipped to the various Red Cross societies in the nine European countries currently receiving assistance. These are Finland, German-occupied Poland, France, England, Latvia, Lithuania, Rumania, Hungary and Yugoslavia. The latter five countries harbor some 122,000 Polish soldiers and civilians who sought refuge there last September.

American Red Cross relief operations in Europe are under the supervision of a commission of two men—James T. Nicholson, from the National Headquarters, Washington, District of Columbia, and Wayne Chatfield-Taylor, former assistant secretary of the treasury. With central offices at Geneva, they are in a position to visit the various relief fronts and personally supervise distribution of supplies and ascertain future needs.

NOTES

Dr. Elliott P. Joslin has recently accepted the honorary chairmanship at Yale University of the Division of Medicine and Public Health of the President's Committee on University Development, succeeding the late Dr. Harvey Cushing. The aim of the committee which Dr. Joslin heads is to secure additional endowment for the medical school so that its facilities may continue to expand, and along with them, its service to the community and the country. The committee also seeks to raise funds for a quadrangle to house medical students.

The appointment of Dr. Charles F. McKhann as professor of pediatrics at the University of Michigan Medical School has been recently announced. Dr. McKhann, who is associate professor of pediatrics at Harvard Medical School, will assume his new duties early this fall.

Dean Stanhope Bayne-Jones, of the Yale University School of Medicine, was elected president of the American Association of Pathologists and Bacteriologists at its recent annual meeting in Pittsburgh. Dr. Bayne-Jones, who succeeds Dr. Carl V. Weller of the University of Michigan, has been vice-president of the organization during the past year and a member of its council since 1937. A member of the executive council of the Association of American Medical Colleges, Dr. Bayne-Jones has been professor of bacteriology at Yale since 1932.

At the recent meeting in Cleveland of the American College of Physicians, Dr. Roger L. Lee, of Boston, was chosen as president-elect. He will assume office, following the expiration of the term of the present president, Dr. James D. Bruce, of Ann Arbor, Michigan, in the spring of 1941.

REPORT OF MEETING

HARVARD MEDICAL SOCIETY

There was a regular meeting of the Harvard Medical Society at the Peter Bent Brigham Hospital on January 9, with Dr. Elliott C. Cutler presiding.

There was one case presentation, by Dr. Harry B. Friedgood. A twenty-nine-year-old single Italian woman first entered the hospital in December, 1938, giving a history of increasing irregularities of menstrual periods since the menarche at the age of fourteen, with a marked change occurring at the age of nineteen. The patient was somewhat obese and hirsute with the onset of the catamenia, but there was a notable increase in both these characteristics ten years before entry. Physical examination on admission revealed a thickset, masculine woman with marked hirsutism of characteristic male distribution, an acneiform eruption of the face and back, and an enlarged clitoris. Blood pressure readings varied from 140 systolic, 90 diastolic to 160, 100. X-ray films showed no demonstrable pituitary, adrenal or thymic abnormality. Ten urinary specimens showed an average excretion of 37 mg. equiv. of androsterone in twenty-four hours, as compared with the normal value of 10 to 12 mg. equiv. In view of the finding of a right lower-quadrant mass considered to be an enlarged ovary and the absence of other localizing signs, a laparotomy was performed by Dr. Robert M. Zollinger. At that time there were found two enlarged ovaries, the right being five times normal size, both were enclosed in thick fibrous capsules. Since the organs were obviously nonfunctioning clinically, as well as useless by appearance, and since such ovaries are known to produce androgens, a bilateral oophorectomy was performed. Postoperatively the androgen level remained at 34 mg. equiv. and there were no other clinical evidences of improvement, with the possible exception of a slight decrease in blood pressure (130 systolic, 80 diastolic) and a questionable decrease in the growth of hair.

From April to October, 1939, no laboratory data were obtained and the patient's symptoms remained essentially unchanged. At the latter time, however, there was an acute attack of pain considered suggestive of either acute gall bladder disease or renal colic. The finding of an elevation of the urinary androgen level to over 50 mg. equiv. and the subsistence of symptoms led to further study, which revealed an androgen level persistently above 50 mg. equiv., supposedly in the range of cancerous lesions. Consequently an exploratory operation in the region of the left adrenal gland was performed by Dr. William C. Quinby in December, 1939, and a questionably abnormal organ removed, with the precarious condition of the patient precluding any further exploration. Tests on six specimens of urine since the operation have revealed an average androgen value of 27 mg. equiv., which is approximately half the preoperative level. This was taken as an indication that, at least in this patient, the urinary androgens originated in the adrenal glands and that no tumor was involved. For in the latter instance, the androsterone values would have either fallen promptly to normal in the case of a left-sided tumor or remained essentially unchanged in the event of a right-sided one.

In reply to Dr. Soma Weiss's question as to the validity of assuming that an elevation of the urinary androgen levels above 50 mg. equiv. indicates a malignant neoplasm, Dr. Friedgood stated that the chemical identity of the excreted androgens was probably a more significant finding. In cancer the percentage of dehydroisoandrosterone approaches 50 per cent of the total urinary androgen output, whereas the usual value is only 5 per cent.

The pathological department reported that the ovaries were very large, with dense fibrous-tissue capsules and no evidence of ovulation. The removed adrenal gland was within normal weight when due account was taken

of a large medullary hemorrhage. There was no evidence of neoplasia in any organ.

The speaker of the evening was Dr. H. Stanley Bennett, whose subject was "The Mechanism of Secretion in the Adrenal Gland." It was pointed out by way of introduction that the adrenal gland in mammals is really composed of two separate organs, each with its own secretion. Although the possibility of there being some chemical interrelation between these parts of the gland has been postulated, the presence of the cortical hormones from isolated nodules of cortex and the probable presence of adrenaline in the abdominal paraganglia obviate the necessity of any such hypothesis, and indeed make it untenable. Furthermore, fish, reptiles and amphibians have no such close spatial relation to these two organs.

Since it has been fairly conclusively demonstrated that the adrenocortical steroids are all derivatives of cholesterol and can maintain adrenalectomized animals and since it has been shown that the ketone fraction of the adrenal gland contains all this biologic activity, it was attempted to determine by color reactions the localization of the biologically active ketones in the adrenal cortex. In order to further clarify the mechanism of secretion, the blood vessel configuration in the gland was presented, for it was concluded that the hormone must exit via this channel since the lymphatics run only to the capsule. The audience was also reminded that the three zones of the adrenal cortex are in reality three phases of the life cycle of the cortical cells, which are formed in the subcapsular region and migrate inward to their senescence in the juxta-medullary portion of the gland.

By employing sudan III and osmic acid, Dr. Bennett was able to differentiate four rather than three zones in the adrenal cortex of the cat. The application of phenylhydrazine or ammoniacal silver solution to frozen sections showed that water-insoluble ketones were confined to the second of these four zones—the outer portion of the fasciculi—and that the biologically active steroids are hence localized in this area, which could be regarded as the secretory zone of the cortex. The specific ketone nature and the solubility properties of the compounds giving rise to the phenylhydrazine reaction were demonstrated by the prevention of the formation of the yellow color of the phenylhydrazones following previous acetone or alcohol extraction or by causing the sections to be immersed in a semicarbazide solution. Further observation of sections in which the cholesterol was precipitated by digitonin showed that the above-mentioned secretory zone is also richest in cholesterol and its esters. This is consistent with Fieser's assertion that cholesterol is a precursor of the steroid hormones. The four zones revealed in the cat's adrenal cortex by these methods were designated as presecretory, secretory, postsecretory and senescent, in accordance with the supposed functional state of the cells comprising the respective zones.

Dr. Bennett exhibited drawings demonstrating the cytology of the various zones, particularly the great increase in cell size and the number of secretory lipid droplets during the secretory phase. The findings were found consistently in all mammals when due consideration was made for slight quantitative variations of species.

A study of the blood supply revealed a rich radial plexiform arrangement of capillaries streaming from the capsule toward the medulla through the cortex.

Dr. Bennett inaugurated the discussion of the medulla by reminding his audience of the chromaffin reaction whereby a number of oxidizing agents will cause that part of the gland which contains adrenaline to be stained brown. This was considered to be due to the oxidation of the adrenaline to an insoluble brown substance and

the intensity of the brown reaction was thought to vary in proportion to the amount of adrenaline in the cells, thus accounting for the patchy character of the staining reaction. Ammoniacal silver solution was used to accentuate the varying color intensity and was of particular advantage in photographing sections of the gland.

A review of the medullary blood supply revealed that it arises from two sources: the cortical capillaries, which drain into an extensive branching venous tree in the medulla, and the direct radial medullary arteries, which pass from the capsule through the cortex to the medulla and break up into a fine capillary bed between the venous radicals in the medulla. A close analysis of the relation of the cells to the vascular system revealed the important fact that there was characteristically a true polarity of cells, with one end of the cell directed toward the arterially supplied capillaries and the other toward the veins. Properly prepared sections showed that the medullary cells were typically arranged as columnar epithelium along the veins, and that this arrangement gives rise to the appearance of the conventionally described cords and whorls in glands fixed by immersion. Further investigation disclosed that the nucleus was always nearer the capillary pole of the cell while the Golgi apparatus and secretion droplets occupied a position between the nucleus and the venous pole. It was concluded therefore, that the venous pole was predominantly secretory, whereas the opposite capillary pole was primarily nutritive. Cytological changes in the cells were correlated with different secretory phases of the cells, and the hypothesis was advanced that the medullary cells go through a series of cycles of secretion, in the course of which one can identify phases of storage of adrenaline, secretion, exhaustion and regeneration.

NOTICES

REMOVALS

ISRAEL KOPP, M.D., announces the removal of his office to 353 Commonwealth Avenue, Boston.

THEODORE J. C. VON STORCH, M.D., announces the removal of his office to the Robert Dawson Evans Memorial Department of Clinical Research and Preventive Medicine, of the Massachusetts Memorial Hospitals, 78 East Concord Street, Boston.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday April 23 in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance) at 8:15 p.m. Dr. Elliott C. Cutler will preside.

PROGRAM

Some Recent Advances in Our Knowledge of the Biliary Tract. Dr. I. S. Ravdin, of Philadelphia.

Medical students and physicians are cordially invited to attend.

BOSTON MEDICAL HISTORY CLUB

There will be a meeting of the Boston Medical History Club at the Boston Medical Library 8 Fenway Boston on Monday evening April 15 at 8:15. Dr. Robert B. Osgood will speak on "Menders of the Maimed."

All those interested in the subject are cordially invited to attend.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, April 17, from 2 to 4 p.m. Drs. Elliott C. Cutler and John Romano will speak on "Headache."

Physicians and students are cordially invited to attend

HARVARD MEDICAL SCHOOL LECTURE

The annual lecture on "The Care of the Patient" will be given by Dr. Charles R. Austrian, of Johns Hopkins University School of Medicine, at the Harvard Medical School, Amphitheater C, on Monday, April 15, at 5 p.m.

COMMUNITY NURSING COUNCIL OF BOSTON

The second annual meeting and luncheon of the Community Nursing Council of Boston will be held at the Young Women's Christian Association, 140 Clarendon Street, Boston, on Tuesday, April 23, at 12:30. Dr. Channing Frothingham will speak on "An Experiment in the Delivery of Medical Care."

The charge for luncheon will be 85 cents. Reservations, sent to the Community Nursing Council of Boston, 80 Federal Street, Boston, should be made by Saturday, April 20.

QUINCY CITY HOSPITAL

The fiftieth anniversary of the founding of the Quincy City Hospital will be celebrated on April 18 and 19. The program is as follows:

THURSDAY, APRIL 18

- 9:00-10:30 (Administration Building) Symposium on Fractures. Dr. A. W. Reggio and associates.
- 10:40-12:00 (Administration Building) Symposium on Obstetrics. Dr. F. L. Good and associates.
- 12:10-1:25 (Administration Building) Appendicitis Cases at the Quincy City Hospital. Dr. J. E. Knowlton.
- 1:30 (Nurses' Dining Room) Steak dinner for the members of the medical staff and of the Norfolk South District Medical Society.
- 4:00 (Administration Building) Blood Dyscrasias. Dr. W. P. Murphy.

FRIDAY, APRIL 19

- 9:00-10:30 (Conference Room, Administration Building) Panel Discussion: Modern surgery of the gall bladder. Conducted by Dr. W. R. Hurley.
- 12:15 (Neighborhood Club) Luncheon, to be followed by:
The Place of the Community Hospital in Any Public-Health Program. Dr. A. S. Pope.
History of Medicine. Tableaux presented by the graduates and students of the School of Nursing.
1940 Trends in Nursing. Elizabeth Sullivan, R.N.
- 7:00 (Neighborhood Club) Formal dinner. Dr. F. R. Burke, toastmaster, invocation by the Rt. Rev. Michael J. Owens, V.F. The scheduled speakers and their subjects are as follows:
History of the Hospital. Dr. C. J. Lynch.
Highlights in the Development of the Hospital. Drs. Burke, Reardon, McCausland, Hurley, Sargent, Adams and Lynch.
Present Day Resume of the Hospital. Mr. G. W. Hart, chairman of the Board of Managers.

The Role of Hospitals in the Progress of Surgery in the Last Half Century. Dr. E. C. Cutler.
Anticipated Future Developments. Dr. J. P. Leone.

NEW ENGLAND SOCIETY OF PSYCHIATRY

The annual meeting of the New England Society of Psychiatry will be held at Danvers State Hospital, Hathorne, Massachusetts, on Thursday, April 25.

PROGRAM

- 10:00 a.m.-1:00 p.m. Inspection of hospital.
- 1:00 p.m. Luncheon and business meeting. Dr. M. Ralph Kaufman will speak on "Factors in Psychotherapy: A psychoanalytic evaluation."

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

Because of the coming scientific session of the Academy of Physical Medicine at Richmond, Virginia, April 24 to 26, there will be no regular scientific program of the New England Society of Physical Medicine this month. Members will meet for a business session at the Hotel Kenmore on April 17.

NEW ENGLAND PATHOLOGICAL SOCIETY

The next meeting of the New England Pathological Society will be held at the Peter Bent Brigham Hospital on Thursday, April 18, at 8:00 p.m. Dr. Hamilton Montgomery, a member of the Section on Dermatology, Mayo Clinic, will speak on the subject "Pathologic Features of Some of the Non-Neoplastic Dermatoses."

Physicians and medical students are cordially invited.

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS

The twenty-fifth annual meeting of the American Association of Industrial Physicians and Surgeons, together with the first annual meeting of the American Industrial Hygiene Association, will be held at Hotel Pennsylvania, New York City, June 4, 5, 6 and 7. This will be a four-day convention intensively devoted to the problems of industrial health in all their various medical, technical and hygienic phases, with particular stress on the prevention and control of occupational hazards. Important programs have been prepared, and technical and scientific exhibits will be a feature. The dinner on Thursday evening, June 6, will be the occasion of the presentation of the William S. Knudsen award for the year 1939-40. The medical profession is not only invited but urged to attend these gatherings as they will be of unusual interest and value to all practitioners interested in industrial injuries and illnesses.

ACADEMY OF PHYSICAL MEDICINE

The eighteenth annual meeting and scientific session of the Academy of Physical Medicine will be held at Richmond, Virginia, April 24, 25 and 26, under the presidency of Dr. Harold D. Corbuser, of Plainfield, New Jersey. The headquarters will be at the Hotel John Marshall, with demonstrations and clinics at the Academy of Medicine Building. Brigadier General Frank T. Hines, chief of the United States Veterans' Administration, will be the speaker at the annual banquet on the evening of April 25. Dr. J. Fulmer Bright, Mayor of Richmond, and other men of prominence will address the public meeting. There will be extensive exhibits. An attractive social program has

been planned for the ladies under the direction of Mrs. Thomas Wheelodon. The session occurs during Garden Week in Richmond.

The scientific program will be open to the medical profession without registration fee.

The program will be forwarded on request addressed to Herman A. Osgood, M.D., Secretary 144 Commonwealth Avenue, Boston.

AMERICAN PUBLIC HEALTH ASSOCIATION

The sixty-ninth annual meeting of the American Public Health Association will be held in Detroit, Michigan October 8-11 with the Book-Cadillac Hotel as headquarters. The Michigan Public Health Association, the American School Health Association, the International Society of Medical Health Officers, the Association of Women in Public Health and a number of other allied and related organizations will meet in conjunction with the association. The Michigan Committee on Arrangements is headed by Mr. Abner Larned, of Detroit. Dr. Henry P. Vaughan, health commissioner of Detroit, is executive secretary.

The annual meeting of the American Public Health Association is the largest and most important health convention held on this continent. It will bring 3500 health officials to Detroit for a series of scientific meetings covering all phases of health protection and promotion. A Health Exhibit will be held in connection with the meeting, and an Institute on Health Education is scheduled prior to the official opening.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY APRIL 14

MONDAY APRIL 15

5 p.m. The Care of the Patient. Dr. Charles R. Austrian. Harvard Medical School, Amphitheater C.

8:15 p.m. Members of the Malmed. Dr. Robert B. Osgood. Boston Medical History Club. Boston Medical Library & Fenway

TUESDAY APRIL 16

9-10 a.m. The Origin, Diagnosis and Treatment of Pityriasis. Dr. Oscar Hirsch. Joseph H. Pratt Diagnostic Hospital.

12 m. Surgery of the Lung. Dr. Edward D. Churchill. South End Medical Club. Headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston.

8:15 p.m. The Heredity of Mental and Nervous Disease and Eugenic Sterilization. Dr. Abraham Myerson. Boston Lying in Hospital, Journal Club meeting.

WEDNESDAY APRIL 17

9-10 a.m. Hospital case presentation. Dr. S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

3-4 p.m. Headache. Drs. Elliott C. Cutler and John Romano. Peter Bent Brigham Hospital.

THURSDAY APRIL 18

9-10 a.m. Gastrointestinal Clinic. Drs. K. S. Andrews, H. H. Lerner and L. M. Aiken. Joseph H. Pratt Diagnostic Hospital.

8 p.m. Pathologic Features of Some of the Non-Neoplastic Dermatoses. Dr. Hamilton Montgomery. New England Pathological Society. Peter Bent Brigham Hospital.

FRIDAY APRIL 19

9-10 a.m. Hospital case presentation. Dr. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

*Open to the medical profession.

April 15-17—American Association for the Study of Goltz. P. 203, issue of February 7.

BOOK REVIEWS

Injuries of the Nervous System Including poisonings Otto Marburg and Max Helfand. 213 pp New York Veritas Press, 1939 \$3.00

The senior author was for many years head of the Neurologisches Institut der Universität, in Vienna, and more recently has been connected with the Montefiore Hospital in New York. His work on the pathology of the nervous system is well known, and he has been one of the outstanding contributors to this subject in the last few decades. A book with such a distinguished man as one of the authors, therefore, needs careful perusal. The subject is carefully investigated with a reference list covering most of the literature published in recent years. One misses, however, one of the most important books on intracranial injuries issued in America in the last few years, namely that by Donald Munro.

The fields of symptomatology, pathology and treatment are considered both for cerebral injuries and for those of peripheral nerves. In addition, there are chapters on electric injuries, caisson disease, trauma as a cause of organic nervous diseases and poisonings. In a book of slightly over two hundred pages, the reviewer believes that the authors have tried to cover too much ground. Much of their material is presented in a sketchy manner, particularly that of the clinical manifestations of injuries and the sections on treatment. The part dealing with pathology is excellent, and there are a number of important illustrations. An interesting chapter deals with the relations between trauma and organic disease. As with most neurologists, the authors take the middle ground, pointing out that trauma may be a factor in almost any structural disease of the nervous system, although the incidence is small.

In general, the book reviews the subjects in a fairly adequate manner. Much of it is written, however, in the on-the-other-hand style, a definite stand is not taken, a position which would have been welcome in view of the well earned reputation of the senior author. The book is well printed, and the illustrations are adequate. There is a moderately extensive bibliography and index. It is a book which no neurologist should fail to read. It makes an interesting preparation for medicolegal testimony. It is not quite extensive enough, however, to be quoted and one hopes that the authors will write a book in the near future covering the subject in detail. There are a few

minor errors in spelling, such as, for instance, the name of Dr. Naffziger.

Diagnostic Signs, Reflexes and Syndromes W. Egbert Robertson and Harold F. Robertson. 309 pp Philadelphia F. A. Davis Co., 1939 \$3.50

This book is a valuable reference work. No one has heretofore undertaken to accumulate in a single volume the various signs, reflexes and syndromes, predominantly eponymic. In this volume they are arranged alphabetically and accompanied by a brief definition.

The appearance of this book is a significant event not because it is a definitive work but rather because it raises an issue which has been a source of controversy in the medical profession. The history of science is replete with manifestations of veneration for its pioneers. Nowhere is it carried to the degree found in the field of medicine. As is evidenced by this book we now find ourselves with a heritage of hundreds of non-descriptive eponyms impinging on the minds of the profession, obfuscating students and burdening medical literature. On the one hand is the sincere realization that the classical descriptions of the original observers warrant historical notation and recognition, on the other hand is the crying need for reorientation and simplification of medical terminology. The latter is illustrated in the following quotation from page 43 of the June, 1934, volume of *International Clinics* (Philadelphia, Montreal, London J. B. Lippincott Company):

Nonhemophilic, nonpurpuric, and nonthrombotic hereditary familial bleeding with or without (telangiectasia) hereditary familial angiomatosis (Rendu-Osler Weber's Disease or Goldstein's Disease), hemophilia, thrombasthenic and thrombopenic purpura, Frank's pseudohemophilia hepatica ("hypoleukia splenico-hepatica") and hemorrhagic capillary toxicosis, Von Willebrand's hepatogenic hemorrhagic diathesis, Jurgen and Von Willebrand's constitutional thrombopathy, David's hemorrhagic (dysendocrinism) disease in women, metropathia haemorrhagica, Glanzmann's familial thrombasthenic purpura, pseudohemophilia, and Biermer's hyperchromic macrocytic anemia, severe hypochromic microcytic anemia have, during recent years, received considerable attention.

Until some simplified form of medical terminology is adopted, it would be well to possess this volume, which is published in a handy size and is thumb indexed.

Civilization against Cancer Clarence C. Little. 150 pp. New York and Toronto Farrar & Rinehart, Inc., 1939 \$1.50

Any author will realize the obvious difficulties expected in writing a short book on cancer for the lay public. The inescapable limits to this subject, theoretical and practical, are so involved in details from all branches of modern science that it requires considerable skill to present the material in concise and understandable language. It must be admitted that the author has accomplished this singular feat, leaving out enough of the detail and selecting facts to support the educational program of cancer control. The book is interesting, contains a minimal amount of personal theories and reflects in a modest way the author's abilities in the field of organized cancer research. It is to be recommended to all and sundry and should prove of value in the dissemination of knowledge in this branch of medicine. The book when read will not frighten anyone, or subject him to any of the unusual fears of neoplastic disease.

NUMBER 16

THE TREATMENT OF EPILEPSY AND OF MIGRAINE*

WILLIAM G. LENNOX, M.D.†

BOSTON

THE treatment of epilepsy and of migraine is a large subject, both in extent and in difficulty. It concerns general practitioners as well as workers in laboratories.

In the United States, assuming there are 100,000 practicing physicians, the average physician should have the care of about five persons with epilepsy and fifty with migraine. The great majority of these persons are not patients, owing in part to the fact that physicians give little interest and less encouragement to would-be patients. A seizure of headache or of a convulsion is looked on as an act of God, against which the medical profession is helpless. This fatalistic attitude born of thousands of years of experience is no longer necessary. Cure is still a word to be used with caution, but some measure of relief is almost always possible.

First, let us examine the linkage of these two disorders, which at first thought are alike only because both occur in attacks, the person in the free intervals being essentially normal. In many respects the two conditions are opposites. Socially, migraine and epilepsy are far apart. Migraine appears oftener in the professional, brain using group and epilepsy in the laboring group. Migraine is respectable, even fashionable; epilepsy is an outcast in society, a Cinderella of medicine. Epilepsy is divided equally between the sexes; migraine is twice as common in women as in men. Epilepsy develops most frequently in infancy and adolescence, migraine in adolescence and beyond. Epilepsy often leads to mental deterioration, migraine does not. Emotional disturbances when present are usually the result of seizures in epilepsy and a cause of seizures in migraine. As a result, migraine patients are more elusive than epileptic patients, many victims of headache seeming to cling to their symptoms. Electroencephalo-

graphic records are grossly abnormal in epilepsy, and in pain free periods show doubtful abnormality in migraine. A treatment of dramatic benefit in one of these conditions fails to benefit the other. In epilepsy the essential lesion is a chemical disorder of neurones of the brain leading to a dysrhythmia of their electrical discharge, in migraine the etiology seems to be a dysfunction of the neuro-vegetative system, leading to abnormal relaxation of cranial arteries and undue stimulation of their sensory nerves. The attacks themselves differ widely in symptomatology—in migraine a gradual onset of hemispherical pain, with gastrointestinal and visual disturbances, in epilepsy a sudden loss of consciousness and involuntary muscular movements.

The principal reason for associating these widely differing phenomena is a generic one: they are inheritance linked. For many years we at the Neurological Unit have been gathering data from patients with epilepsy and with migraine, and also from samples of the population. I need not wade through a sea of statistics. A few statements will demonstrate the familial coincidence of the two conditions.

Among patients coming for treatment of migraine, the incidence of seizures was twelve times the incidence of seizures in the control group. Among patients coming for treatment of epilepsy the incidence of migraine was nearly twice the incidence of migraine in the control group.

As for the family histories of these patients, among the immediate relatives of migrainous patients epilepsy occurred three and six-tenths times oftener than among the relatives of the control group. Among the immediate relatives of epileptic patients, migraine occurred twice as often as among the relatives of the control group. If the patient had epilepsy, epilepsy was reported in 23 per cent of his near relatives. If the patient had migraine, epilepsy was reported in 1.8 per cent of his near relatives. (The incidence of epilepsy in

*Presented at the annual meeting of the New Hampshire Medical Society, Manchester, June 8, 1939. From the Neurological Unit, Boston City Hospital, and the Department of Diseases of the Nervous System, Harvard Medical School.
†Assistant professor in neurology, Harvard Medical School; visiting neurologist, Boston City Hospital.

the general population is approximately 0.5 per cent)

One further piece of evidence may be brought forward. If migraine bears a generic relation to epilepsy, the incidence of migraine among the relatives of patients should be greater in the so-called idiopathic epileptic than in the symptomatic epileptic group. To test this point the epileptic patients were divided into two groups, those without and those with evidence of brain injury antedating the onset of seizures. The incidence of migraine in members of the immediate family of the idiopathic group was 31 per cent, whereas in the symptomatic group it was only 1.9 per cent. The corresponding incidence of epilepsy among the relatives of the idiopathic group was 2.5 per cent, and of the symptomatic group 1.4 per cent.¹

This statistical evidence would seem to establish a definite relation between migraine and epilepsy. Obviously the two conditions are not twins, or perhaps even brothers. They are cousins, but not many times removed. Knowledge of one should throw light on the other. Any prohibition against marriage for the purpose of decreasing epilepsy should logically apply to migrainous as well as to epileptic patients.

TREATMENT BASED ON ETIOLOGY

Discussion of individual treatment cannot be concise and simple, because the causes of epileptic or migrainous seizures are complex and vary in different patients, and in the same patient at different times. I^{2,3} have likened migraine and epilepsy each to a reservoir which periodically fills and overflows its banks, the overflow representing the attack. Each reservoir is fed from underground streams representing both the fundamental and the contributing causes of the attacks.

As has been suggested by the statistics just quoted, the fundamental cause of both epilepsy and migraine is an inherited predisposition to the disorders. The logical prophylactic treatment is eugenic. Effective treatment from this direction has not heretofore been possible, since it is the predisposition and not the disorder itself that is inherited, and since there has been no means of detecting a predisposition to epilepsy or migraine in persons without these symptoms. Recently, however, the Gibbises and I⁴ found that 60 per cent of the near relatives of epileptic patients examined presented abnormalities in their cortical electrical records. Relatives with abnormal brain waves outnumbered those with a history of seizures about twenty to one. Therefore, for eugenics to be really effective the twenty per-

sons with cortical dysrhythmia, and not merely the one person with symptoms of epilepsy, should remain single. The same prohibition should apply also to the 10 per cent of the population who are not related to epileptic patients, and who yet have a dysrhythmia presumably indicating a predisposition to epilepsy, or to one of the other clinical disorders characterized by dysrhythmia.

As an offset to this gloomy subject, the important influence of a normal parent should be emphasized. Assuming that 10 per cent of the population have cortical dysrhythmia, by the law of chance only about 1 per cent of married couples would both have dysrhythmia. Yet 35 per cent of the pairs of parents of epileptic patients examined by us exhibited dysrhythmia of both parents. If an epileptic patient will choose a partner whose brain waves are normal, the chance of his having an abnormal descendant is much less than that accompanying the mating of two persons who are without symptoms but have abnormalities of their electroencephalographic records. Thus by use of a laboratory technic the medical profession can answer some of the perplexing questions of heredity. Hope of racial benefit from the application of this new knowledge is limited by the fact that social groups most in need of eugenics do not make use of it.

Even if a predisposition to epilepsy or migraine is present, the syndrome may not appear without the aid of precipitating influences. As has been stated, the character, number and relative importance of these factors vary in different patients. In epileptic patients injury of the brain is most important. Examinations must include procedures designed to disclose lesions of the brain, such as tumors, trauma, meningeal infections and congenital defects. In cases presenting jacksonian seizures (convulsions beginning locally without loss of consciousness), pneumoencephalograms should supplement the routine physical, neurological, spinal-fluid and roentgen-ray skull examinations. When intracranial lesions are demonstrable, the only treatment available is surgical, except that the insufflation of air required in making pneumoencephalograms is sometimes temporarily helpful.

Although the physician's main interest is centered in the brain, he cannot neglect the body, which houses the brain. Improvement in general physique is oftentimes associated with improvement of symptoms. Even less can the social and psychological factors be forgotten. Though the patient may not be rid of his fits, his life may be happy and useful if he is given the opportunity to preserve his self-respect and develop his abilities.

The sufferer from migraine has neither brain

injuries nor social stigmas with which to contend. In the majority of cases the galaxy of symptoms gravitates about the autonomic nervous system and those factors and occasions contributing to "nerve strain." In spite of a heredity that cannot be eradicated, many patients can be rendered symptom-free by removal of worries or fatigue, by lessening emotional stresses or by regulation of habits or improvement of physique. In women, because of the close correlation of headache attacks and menses, the freedom during pregnancy and the permanent relief with menopause, dramatic results might be expected to accrue from administration of hormones or the induction of artificial menopause. The latter expedient usually brings disappointment, but sometimes the administration of large amounts of Theelin seems beneficial.

TREATMENT BY GENERAL MEASURES OR DRUGS

The items of treatment mentioned are designed to remedy defects in the individual patient uncovered by the thorough study that he or she has supposedly received. Details of treatment for individuals would require more time than I have at my disposal. In addition to the correction of determined defects, there are certain measures that may be tried with all patients.

The study of patients with epilepsy has shown that certain alterations of physicochemical conditions in the body will decrease the liability to seizures. Apparently the changes are not specific, but act by decreasing nervous irritability and thus raising the seizure threshold. These measures are acidosis, dehydration, complete oxygenation and increased concentration of sugar, calcium and carbon dioxide in the blood and brain. Many of these have only laboratory application, but induction of acidosis in children by means of a ketogenic diet is of proved value. Some clinicians have faith also in dehydration, secured by drastic limitation of fluid intake.

Sodium Diphenyl Hydantoinate

Main reliance in the control of seizures has been the use of the sedative drugs, bromides and phenobarbital. Recently, however, Putnam and Merritt⁶ have demonstrated the value of sodium diphenyl hydantoinate, a drug which at present answers to the trade name of Dilantin Sodium. This has two points of advantage over bromides or luminal.

First, sodium diphenyl hydantoinate is not a sedative, and therefore its use in maximum doses is not accompanied by the dulling of mental faculties that is often a distressing feature of the drug therapy of epilepsy.

Second, for most patients with epilepsy, and during the two years in which it has been used, this

drug has proved more effective than others in the control of seizures. Merritt and Putnam⁶ have recorded 227 patients treated for more than two months. Because sodium diphenyl hydantoinate is not equally effective in all types of seizures, they have computed results for the three main types. In patients having psychic, grand mal and petit mal seizures the attacks were definitely decreased in 85, 74 and 59 per cent respectively. This improvement was over and above whatever benefit had been obtained by previous treatment—usually with phenobarbital. The favorable results were particularly notable in the case of psychic seizures, which are especially disquieting and may be made worse by heavy phenobarbital medication. On the other hand relatively few patients with petit mal were benefited, and some were actually made worse.

The administration of sodium diphenyl hydantoinate must be more carefully supervised than that of the sedative drugs. At the beginning one capsule containing 0.1 gm (1½ gr) is given three times a day after meals. The amount is slowly increased till the seizures are under control or

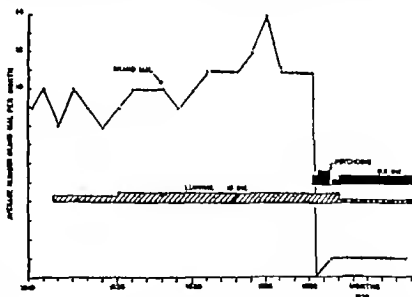

FIGURE 1 Record of Convulsions during Twenty Years in Patient C H

The abscissa represents time in years before January 1939 and in months thereafter. The ordinate represents the average number of grand-mal convulsions per month. Dosage of phenobarbital (luminal) and of sodium diphenyl hydantoinate (Dilantin) is indicated on the chart.

toxic symptoms appear. Six capsules a day seems to be the limit of tolerance. The commonest toxic symptoms are ataxia or tremors, gastric pain or distress, skin rashes, hypertrophy of the gums and psychic upsets. To overcome these untoward symptoms the amount of medicine may need to be temporarily reduced. Persistence will oftentimes carry the patient through temporarily distressing symptoms. Although sodium diphenyl hydantoinate often proves of no benefit, improvement when it does occur may seem miraculous.

A young woman's parents have recorded twenty-two hundred severe convulsions in the course of the last twenty years. As may be seen in the accompanying chart, the number of seizures per year remained remarkably constant and was not influenced by any of the treatments which other physicians and I at various times tried. Phenobarbital was of some benefit and from 1½ to 3 gr was taken daily throughout the period. In January, 1939, the patient was given 0.3 gm of sodium diphenyl hydantoinate. Very soon she went into a psychotic state, which persisted for twelve days. Medication was stopped, but was resumed at the rate of 0.2 gm daily as soon as the psychosis cleared. In the subsequent seven months the patient had only seven convulsions, and her depressed mental state, which I had considered permanent, perceptibly cleared.

Ergotamine Tartrate

In the case of migraine, a drug has in recent years come into use that is equally dramatic in its action.^{7, 8} This is ergotamine tartrate, sold under the trade name of Gynergen. In approximately 90 per cent of patients who are having an attack of migraine and who are given a parenteral injection of the drug, the headache and other symptoms disappear as by magic. That the action of the drug is specific, and not merely that of a pain sedative, is proved by the fact that nonmigrainous headaches are not ordinarily benefited by ergotamine.⁹ The dose is 0.5 mg, —the contents of an ampule, —injected into a vein, muscle or the subcutaneous tissue at the onset of the symptoms. In 45 per cent of the cases there is associated nausea and vomiting. The occasional patient complains of extreme lassitude or of muscle soreness, or rarely of precordial pain. Ergotamine tartrate comes also in 1-mg tablets. Five to ten milligrams may be taken in the course of several hours for a headache attack. In addition to the probability of its being vomited, the drug is poorly absorbed from the intestinal tract, and unless the headache is a mild one its termination is not to be expected from oral administration.

During the last three years we have also used a newly isolated alkaloid of ergot called ergonovine. This fraction of ergot is more prompt and potent than ergotamine tartrate in promoting uterine contractions. For migraine, however, the drug is much less dramatic in its therapeutic effect. Of 54 patients given ergonovine by injection, only 39 per cent were completely relieved.³ However, those patients whose headaches are less stubborn and who have relief from ergonovine prefer it to ergotamine, for the nausea and vomiting are less

pronounced. Also, ergonovine is apparently readily absorbed from the gastrointestinal tract, and the minority of patients who are helped by the drug may obtain relief from its oral use. In my series, 21 per cent obtained no relief when ergonovine was injected, and 33 per cent no relief when it was taken by mouth. The proprietary names of ergonovine are various: Ergometrine, Ergobasine Tartrate, Ergotrate, Ergoklonin. Doses are approximately the same as that for ergotamine tartrate. In the majority of cases, continued use of ergot does not make subsequent headache less severe or less frequent.

Presumably the mechanism of pain production is the same in all patients. The work of Graham and Wolff¹⁰ indicates that relief of migraine headache by ergotamine is attended by coincident decrease in the pulsation of the temporal arteries. Logically help may be expected from surgical interference with the sensory nerve supply to branches of the external carotid artery.

PERSISTENCE IN TREATMENT

The physician who undertakes the treatment of either migraine or epilepsy must prepare for a long campaign and must exercise and develop in his patient the gifts of patience, resourcefulness and hope. No matter how happy the patient may be because of the termination of single attacks, the physician has no right to rest on his oars. The eradication of the cause must still be the goal. In the electroencephalogram we have a laboratory measurement of the patient's progress. Probably supervision and treatment should continue so long as brain waves are abnormal. The physician who treats either of these stubborn conditions is justified in offering his patient the consolation of hope. In the last few years, the study of migraine and of epilepsy has brought a better understanding of the mechanisms involved and of new therapeutic agencies. Continued cultivation of this field should yield further fruit.

SUMMARY

The genetic relationship of epilepsy and migraine and certain methods of treatment are discussed, particularly the use of ergotamine tartrate (Gynergen) in migraine and sodium diphenyl hydantoinate (Dilantin Sodium) in epilepsy.

DISCUSSION

DR. CARLETON R. METCALF, Concord: Is oxygen of value in migraine?

DR. LENNOX: I think it may be, if given over long periods. You refer, probably to the report from the Mayo Clinic, where a special type of inhaler has been constructed. In our clinic, Dr. von Storch has secured the apparatus and finds that certain patients are helped by prolonged inhalation of 100 per cent oxygen. Oxygen causes a constriction of cerebral arterioles, which may explain its beneficial action.

DR. W. J. P. DYE, Wolfeboro: In the use of ergotamine tartrate, how long does the effect of the drug last and how often does it have to be repeated?

DR. LENNOX: The drug aborts the attack—that is, it stops the pain and other symptoms, and the patient is over that particular attack. It needs to be repeated when the next attack comes along, which may be in a month or may be the next day. When attacks recur several times a week, the doctor is a good deal concerned to know whether repeated doses of ergotamine tartrate might produce arterial spasm and gangrene. We have had no such trouble in our cases and many of the patients have taken the drug for several years, several times a week and sometimes even daily without any worse symptoms than some tingling of the fingers. Patients should be observed closely for any effect on blood pressure and on the circulation of the extremities.

A PHYSICIAN: Does allergy have much effect on migraine, or is its alleged action purely psychological?

DR. LENNOX: Migraine has been defined by some as an

allergic condition. We, however, have seen no more allergy in our patients than in the general population, nor have we seen success in treatment along allergic lines. I am not convinced that allergy plays a part either in migraine or in epilepsy.

A PHYSICIAN: What is the action of Dilantin? Also, can the electroencephalogram of petit mal be differentiated from that of grand mal?

DR. LENNOX: Dilantin does not act as a general sedative but just how it works is for future research. It has an effect on the electrical waves of the brain though often times the extent of the improvement of brain waves does not parallel the improvement in symptoms. The electroencephalogram during grand mal is characterized by fast, spiky waves, and during petit mal by alternately fast and slow waves. Behind the different rates of brain waves are differing chemical states of the brain. Patients having only grand mal seem to have a high carbon-dioxide content of arterial blood, and those with only petit mal a low one.

A PHYSICIAN: Do you think that epileptic patients should be allowed to marry?

DR. LENNOX: The factor of inheritance is probably no greater in epilepsy than it is in diabetes or cancer or perhaps tuberculosis. Epileptic patients should not be singled out. A person with epilepsy may have highly desirable qualities along with it. An epileptic patient has one out of forty near relatives who are epileptic—the non-epileptic patient has one out of two hundred. As I have explained, the normal "carriers" of epilepsy are as important genetically as the epileptic patient. If the latter will choose a mate whose brain waves are normal, the chance of having an epileptic person among his descendants is greatly reduced; this will probably not occur for many generations.

A PHYSICIAN: Does the water balance have any effect?

DR. LENNOX: Yes. In certain patients, limitation of fluid—the dehydration treatment—seems to be of value.

A PHYSICIAN: What about the salt free diet?

DR. LENNOX: That is of value only when giving bromides. With a limited chloride intake, bromides are more readily retained by the body and therefore not so much bromide needs to be given. A salt free diet merely reduces the patient's bill at the drugstore.

URINARY INFECTIONS IN INFANTS AND CHILDREN*

BENJAMIN W. CAREY, M.D.†

DETROIT

THIS paper proposes to point out some of the important contributions to the knowledge of renal damage resulting from chronic urinary infections, the principal causes of pyuria and urinary infection, the important steps in the diagnostic approach to a patient with pyuria, and an outline of therapy. The recognition of congenital anomalies and infection in the urinary tract has become such a vital part of the diseases of infants and children that it is desirable for us to review certain phases of the problem. The impetus to this situation has developed first and chiefly from the emphasis placed on chronic urinary infections as a cause of renal damage and hypertension in childhood, adolescence or adult life, second, from the development of better methods of diagnostic approach to the genitourinary tract, and third, from the use of the newer therapeutic agents, mandelic acid and sulfanilamide.

Longcope and Winkenwerder¹ were among the first to report hypertension in the uremic stage of cases of chronic pyelonephritis. Butler² called attention to the facts that hypertension may be associated with pyelonephritis before there is demonstrable diminution in renal function and that hypertension secondary to unilateral pyelonephritis may disappear after removal of the involved kidney. The problem of hypertension associated with chronic pyelonephritis has been thoroughly studied by Weiss and Parker.³ These writers emphasized many important facts, such as the following: pyelonephritis is probably responsible for at least 15 or 20 per cent of cases of malignant hypertension, chronic or healed pyelonephritis occurs more frequently than does chronic glomerulonephritis, the hypertension of pyelonephritis can be independent of the activity of the renal infection, and often advances when the disease is in the healed stage, pyelonephritis is one renal disease that lends itself to effective treatment in its incipient stage. The things to remember from these excellent studies are that, first, every patient with an infection in the urinary tract should be subjected to thorough diagnostic study in order to find a possible congenital or acquired cause underlying the infection, second, adequate treatment of the infection and its cause should be instituted, and third,

careful follow up of every patient should be maintained, so that a recurrence of the infection may be promptly handled and subsequent renal damage be prevented.

DIFFERENTIAL DIAGNOSIS OF URINARY INFECTIONS

It is relatively unimportant to elaborate in detail the various clinical conditions that infection in the urinary tract may simulate, as there are many textbooks readily consultable for a complete discussion. The presence of an unexplained fever, abdominal pain, even vomiting or diarrhea, or symptoms referable to the genitourinary tract such as frequency, dribbling, enuresis or painful urination, should lead one to suspect infection in the urinary tract, and to institute proper steps to confirm or rule out such a diagnosis.

URINALYSIS

The finding of leukocytes or bacteria or both in a centrifuged specimen of urine usually suffices to establish the diagnosis of pyuria or infection in the urinary tract. However, this statement must be qualified and analyzed. During the course of many acute infections in locations other than the genitourinary tract, it is not uncommon to find a few leukocytes in the urinary sediment after rapid centrifugation. Certainly such a finding does not signify infection in the urinary tract. The specimen of urine must always be examined immediately after it has been obtained, specimens allowed to stand in open, unsterile containers at room temperature may rapidly develop a heavy growth of contaminating bacteria. Routine urinalysis, performed by a laboratory technician unfamiliar with the patient, may give one a false impression as to the importance of elements in the urine. It is always necessary to examine repeated specimens before establishing the diagnosis of pyuria or infection in the urinary tract, preferably obtained by catheterization in girls and after careful cleansing of the penis in boys. The physician should examine the specimen of urine himself rather than rely on the word of another. It should be remembered that a negative sediment from a single uncentrifuged urine specimen does not exclude the presence of pathologic elements in the urine. In the event that abnormal elements are found in the sediment, anomalies or infection in the vagina or urethra should be excluded before proceeding further with the investigation.

*Presented at the New England Postgraduate Assembly, Cambridge, Massachusetts, November 1, 1939. From the Children's Hospital of Michigan and the Department of Pediatrics, Wayne University College of Medicine, Detroit.

†Assistant professor of pediatrics, Wayne University College of Medicine; bacteriologist, Children's Hospital of Michigan, Detroit.

CAUSES OF PYURIA AND URINARY INFECTION

There are many congenital and acquired factors that may be the direct or indirect cause of pyuria and urinary infection. The most important of them are as follows:

Pyelonephritis
Hydronephrosis
Calculi in the kidney, ureter, bladder or urethra
Renal tuberculosis
Renal tumor
Perineal infection, such as tuberculosis of the spine
Aberrant vessel obstructing the ureter or some other portion of the urinary tract
Ureteral kink
Penurethral infection
Hydroureter
Ureteral stricture
Diverticulum of bladder or urethra
Neuromuscular disease of bladder
Congenital valves at the ureteral orifices
Ureteral meatus stricture
Bladder tumor
Cystitis
Obstruction of the neck of the bladder
Prostatitis
Hypertrophy of the verumontanum
Congenital valves in the posterior urethra
Penurethral infection
Urethritis and stricture
Stenosis of the prepuce or urethra
Cervicitis
Foreign body in the vagina
Vaginitis

DIAGNOSIS OF PYURIA AND URINARY INFECTION

The first step in securing information as to the presence of a urinary infection, after excluding anomalies or infection of or about the external genitalia, is to obtain a catheterized specimen of urine for microscopic examination and culture in order to determine the causative organism. Catheterization will furnish information as to the volume of residual urine, and may help to exclude the presence of a posterior urethral anomaly.

The next step is to secure a flat roentgenogram of the abdomen including the bladder. This procedure may give information as to the size of the kidneys, and the presence of large intra-abdominal masses or calculi in the urinary tract. As a measure of kidney function, valuable information may be secured by determining the blood pressure and the nonprotein nitrogen in the blood.

These procedures may be quite adequate if the infection is the initial attack or is secondary to some other infection such as pneumonia but in the event of recurrent attacks of infection or an infection of long duration, further studies of the urinary tract and function of the kidneys are desirable. These should include a test for the concentrating power of the kidneys and an intravenous pyelogram, if evidence is at hand of dimin-

ished kidney function or anomalies in the urinary tract, it may be necessary to obtain a urea clearance test, and to perform a cystoscopy and obtain retrograde pyelograms. If the infection is the patient's first attack, and it has been demonstrated that the kidneys have normal concentrating ability and that the blood nonprotein nitrogen, blood pressure and intravenous pyelograms are normal, medical treatment may be instituted without performing cystoscopy and retrograde pyelography.

If unsatisfactory evidence has been obtained from intravenous pyelography, a cystogram may be done prior to retrograde pyelography. Information may be secured from this procedure as to the presence of a diverticulum of the bladder, tumor of the bladder or post-urethral obstruction.

Indications for cystoscopy may include evidence from intravenous pyelography of impaired function of one kidney or a portion of a kidney, absence of a part of the urinary tract, evidence of an anomaly of the bladder or urethra, and the necessity of examining and culturing the urine and determining the function of each kidney separately. However, if inoperable bilateral anomalies or abnormalities are observed in the intravenous pyelograms, or if the kidney function is markedly diminished, cystoscopy may be contraindicated.

In order to obtain successful intravenous pyelograms in children, certain general principles must be followed. It is necessary to restrict the fluid intake for some hours preceding injection of the dye so as to obtain a specific gravity of at least 1.020 in the urine, in order that the dye may be sufficiently concentrated to give proper visualization of the urinary tract. The presence of an excess amount of gas in the small intestine will obscure the dye in the urinary tract, and measures must be taken, such as mild laxatives, cleansing enemas or even drugs, to increase intestinal peristalsis and control excessive amounts of gas. A roentgenogram of the abdomen should be taken prior to injection of the dye, and if excessive amounts of gas are seen the procedure should be postponed until the gas can be eliminated. The dose of the intravenous dye should be adequate, and it should be remembered that the dose for infants is larger than that for older children.

The following list presents in summarized form the essential diagnostic procedures in the study of a patient with pyuria or urinary infection.

1. Examination of the external genitalia for the presence of congenital anomalies, inflammation, purulent discharge or foreign body.
2. Urinalysis (voided specimen unless the patient is a girl with a vaginal discharge).
3. Catheterization (urethral anomalies, residual urine, urinalysis and culture of urine).

- 4 Kidney function tests
 - a Blood pressure.
 - b Concentration test (the specific gravity of the urine should be at least 1 020)
 - c Nonprotein nitrogen of the blood.
 - d Urea clearance test if a, b or c are abnormal
- 5 Roentgenogram of the abdomen
- 6 Intravenous pyelogram.
- 7 Cystogram (especially if bladder abnormalities are suspected)
- 8 Cystoscopy
 - a Appearance of the urethra and bladder
 - b Ureteral catheterization, to determine the function of each kidney separately, culture and examination of urine from each kidney separately
 - c Instillation of dye for roentgenograms

The importance of the early recognition and treatment of congenital anomalies producing obstruction in the urinary tract and subsequent renal damage should be emphasized. The following case demonstrates how rapidly renal damage may occur following an obstructing congenital anomaly.

W B, a male infant, 3 months of age, was admitted to the hospital on June 20, 1939, with the chief complaints of difficulty in feeding and increasing pallor of the skin since birth. The birth was normal, and the birth weight was 8 pounds. The patient was given an evaporated milk formula but frequently refused it. Vomiting occasionally occurred after the feeding. Several changes were made in the formula, but the refusal and vomiting continued. The mother noted that the infant's skin had become increasingly pale since birth and that he seemed "feverish" frequently during the month preceding admission. Two weeks prior to entry a severe cough developed, which was spasmodic in character and was occasionally followed by vomiting. The infant seemed to be dyspneic for about 2 weeks prior to entry.

Physical examination revealed a fairly well-nourished infant with marked pallor of the skin who appeared acutely ill. The weight was 11½ pounds. The respiratory rate was increased, and the rectal temperature 101°F. The remainder of the physical examination was essentially negative except the abdomen. In the latter there was moderate distention, and a large, smooth, hard mass, which did not move with respiration, was palpable in the right flank. The tip of the spleen was palpated at the left costal margin.

Urinalysis (voided specimen) showed a clear, yellow urine without the presence of albumin, sugar or acetone, and no leukocytes, erythrocytes or casts in the sediment.

Examination of the blood revealed the presence of a severe secondary anemia. Other laboratory procedures were negative.

A roentgenogram of the chest showed considerable pneumonic infiltration in the central lung fields, with extension into both upper lobes. A film of the abdomen was unsatisfactory owing to obscuration by distended loops of intestine.

The patient received a blood transfusion the day following admission, and treatment of the pneumonia with sulfapyridine was instituted. However, his condition became steadily worse. The signs of pneumonia progressed. The rectal temperature varied between 99 and 105°F. It was suspected that the mass palpated in the right flank was an enlarged kidney, but because of the gravity of the condition, further diagnostic procedures, such as kidney visual-

ization and renal function tests, were not attempted. Death occurred on the 5th day.

An autopsy revealed the presence of enlarged kidneys, the right being larger than the left, and on section extensive hydronephrosis and pyonephrosis were seen, with almost complete destruction of the substance of the kidney. Both ureters were markedly dilated and the bladder wall was hypertrophied. On section of the posterior urethra the verumontanum was found to be hypertrophied and practically filled the lumen of the urethra. The lungs showed extensive bilateral pneumonic infiltration and patches of consolidation.

Although the immediate cause of death in this patient was the pneumonia, undoubtedly the obstruction in the urethra was the primary factor in the chain of events leading to the chronic urinary obstruction and infection, the renal destruction, the secondary anemia and, finally, the pulmonary infection and death. An interesting and important point for emphasis was the normal urinalysis on the day of admission. This confusing finding may occasionally occur, and demonstrates the necessity of repeated examinations of the urine before excluding the diagnosis of pyuria.

TREATMENT OF URINARY INFECTIONS

Many drugs have been used in the treatment of infections in the urinary tract. With the advent of mandelic acid and sulfanilamide these drugs have almost entirely replaced the older urinary antiseptics, and most of the latter are now only of historical interest. Both sulfanilamide and mandelic acid are necessary in therapy, as each drug possesses peculiar advantages.

In considering the use of mandelic acid it is necessary to remember that prolonged urinary infection or the presence of congenital abnormalities in the urinary tract may result in marked renal damage, this in turn will not allow sufficient con-

TABLE 1 Dosage of Mandelic Acid and Fluid Restriction According to Age

| AGE | TOTAL FLUID EACH 24 HOURS | MANDELIC ACID (DAILY DOSE) |
|---------|---------------------------|----------------------------|
| yr | cc | grm |
| Under 1 | 450 | 3 |
| 1-2 | 500 | 4 |
| 3-6 | 500 | 5 |
| 6-9 | 600 | 6 |
| 9-12 | 800 | 8 |

centration of the urine, and the proper degree of urine acidity will not be attained. The drug is administered in the form of a 10 per cent elixir of ammonium mandelate. The total daily dose is estimated so that a 1 per cent concentration of mandelic acid in the urine may be constantly maintained. It is necessary to restrict the fluid intake of the patient in order to maintain this concentration. Table 1 shows the fluid restriction and daily dose of mandelic acid for various age groups.

The acidity of the urine should be checked daily in order to make sure that the pH is at the necessary level of 5.5 or below, using chlorphenol red as the indicator. Occasionally it may be necessary to supplement the mandelic acid with a daily dose of an acid salt, such as ammonium chloride, in order to obtain a urine that is sufficiently acid. The sediment of a centrifuged specimen should be examined daily to detect the appearance of erythrocytes or casts. If these elements appear, having been previously absent, an irritant effect of the mandelic acid on the kidney may be occurring and the dose of the drug must be reduced or discontinued promptly. The mandelic acid should be continued for at least a week after the urine culture has become sterile. A limit of three weeks is placed on the continuation of therapy, because if sterilization of the urine has not occurred within this time it is not likely to occur by prolongation of therapy. Mandelic acid is effective against infections caused by organisms of the colon bacillus group and by *Streptococcus faecalis*. The drug is not effective against infection due to *Bacillus proteus* because this organism is always accompanied by an alkaline urine, and it is impossible to attain the proper acidity of the urine necessary for bactericidal action by the mandelic acid.

Sulfanilamide should be administered orally, accompanied by equal or larger doses of sodium bicarbonate. The dosage of sulfanilamide is usually 1 gr per pound of body weight every twenty-four hours. It is desirable to attain a concentration of free sulfanilamide in the urine of 100 to 300 mg per 100 cc., and to maintain the alkalinity of the urine at pH 7.4 or above. The pH can be easily checked by testing a specimen of urine with phenol red as the indicator. As it is difficult to obtain complete twenty-four hour collections of urine from infants and small children for sulfanilamide determination, it is simpler to maintain the blood concentration of free sulfanilamide at a level of 10 to 12 mg per 100 cc. A slight restriction of the fluid intake is desirable in order to maintain the correct urine concentration of sulfanilamide. In infants the daily fluids should be limited to 400 or 500 cc., and in older children to 1000 or 1200 cc. A culture of the urine should be obtained about three days after the sulfanilamide has been started, and at intervals of two or three days until the culture remains sterile. The full dosage should be maintained for at least two days after the culture becomes sterile, then decreased to about half the original amount, and continued for two or three days in order to prevent recurrence of the infection.

The patient should be observed daily for evidence of toxic reactions to the sulfanilamide, such as fever, a skin rash, hemolytic anemia, leukopenia, headache and mental confusion, nausea and vomiting and abdominal pain. If any of these reactions occur, it is desirable either to reduce the dose of the sulfanilamide or to discontinue it. Sulfanilamide is effective against infections caused by organisms of the colon bacillus group, staphylococci, beta hemolytic streptococci, *B. proteus* and a few strains of *Streptococcus faecalis*. Sulfanilamide has one distinct advantage over mandelic acid in that it may be administered during the acute febrile stage of the urinary infection.

A brief summary of the dosage and plan of administration of sulfanilamide is as follows:

Dose of sulfanilamide 1 gr per pound of body weight every 24 hours.

Dose of sodium bicarbonate 1 gr or more per pound of body weight every 24 hours.

Total fluid intake every 24 hours

Infants not over 400 to 500 cc.

Children not over 1000 to 1200 cc.

Urine pH 7.4 or higher

Sulfanilamide concentrations

Urine, 100 to 300 mg. per 100 cc.

Blood, 10 to 12 mg. per 100 cc.

SUMMARY

Neglected cases of pyuria and urinary infection may result in severe renal damage and malignant hypertension.

The diagnosis of pyuria or infection in the urinary tract must be made with proper clinical and laboratory procedures.

Completeness of examination of the genitourinary tract must be emphasized.

Adequate therapy of the urinary infection with mandelic acid or sulfanilamide or both, following proper bacteriological study of the organism responsible for the infection, must be instituted, and maintained until repeated cultures of the urine prove that the infection is cured.

Thorough follow-up of patients examined and treated for urinary infections must be maintained. Recurrences of the infection may occur even after apparent successful treatment, and it is important to relieve the kidneys of further assaults as promptly as possible.

INGUINAL HERNIORRHAPHY IN THE AGED[†]

An Analysis of One Hundred Consecutive Cases In Patients Over Sixty-Five Years of Age

THOMAS B. QUIGLEY, M.D.[†]

BOSTON

IN A previous communication,¹ attention was called to the rapid increase in the proportion of aged persons in the population and to the fact that, in the near future, an increasing number of aged individuals can be expected to present themselves with conditions requiring surgical treatment.

Inguinal hernia, since not only its frequency but its danger increases considerably with each decade (Figs. 1, 2 and 3), becomes a surgical condition of

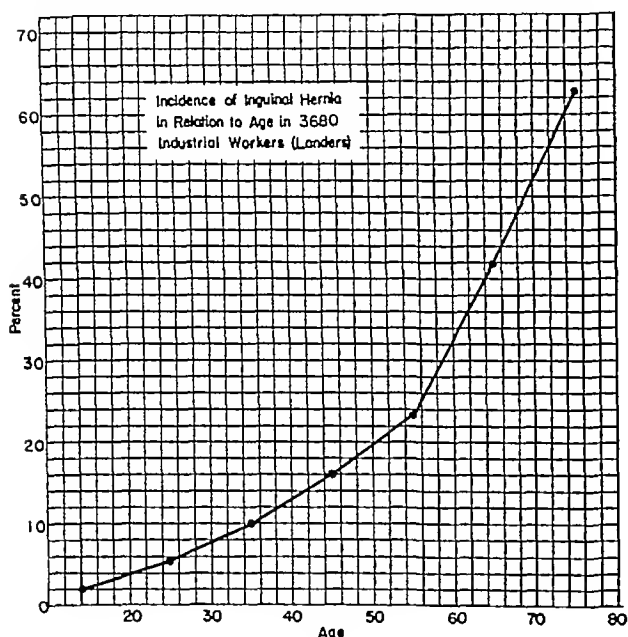

FIGURE 1

Curve constructed from figures given by Landers (*Age incidence of hernia* Indust. Med 7 671, 1938)

particular interest in the aged. Also, the analysis of a series of cases is facilitated by the standardization of the operative procedures employed in its repair.

One hundred consecutive cases in patients over the age of sixty-five were studied from the records of the Peter Bent Brigham Hospital. The average age was 69.8 years. The series included 96 men and 4 women. One hundred and thirty-four hernias were repaired in one hundred and ten operations through one hundred and thirty incisions. There were almost exactly the same number of right and left hernias. The proportion of indirect

to direct was approximately two to one. Eight were recurrences after previous operations. In 30 cases there were bilateral hernias. Four sliding hernias occurred in the series—three left and one right. One operative death occurred, due to pulmonary embolism. The patient, a seventy-five year-old man, succumbed on the twenty-third day after the second of two elective operations carried out under local anesthesia for bilateral hernias. There had been symptoms of pulmonary infarction on the tenth and eighteenth days. The diagnosis was confirmed by necropsy.

In 10 cases operation was imperative, for incarceration in 7 and for strangulation in 3. All the patients recovered, only 3 developed complications: one developed a severe cough, in another case the wound became tender and indurated, and the third patient was disoriented for twenty-four hours after operation.

With regard to the remaining 90 patients, for whom operation was an elective procedure, the reasons for seeking surgical aid are of interest. Twenty of these were undoubtedly influenced by one or more episodes of incarceration, but for the great majority the hernia appears to have become simply an intolerable chronic inconvenience. Of 67 patients who had worn a succession of trusses for an average of 9.4 years, only 12 were satisfied with their appliances at the time of admission to the hospital. In one case the truss had produced a considerable degree of ulceration of the skin. Although operation was delayed until this had healed, the patient developed the only gross wound infection in the series.

In many cases the annoyance of the hernia, from the patient's point of view, outweighed the manifestations of much more serious disease. This is well illustrated by the following case.

J. Y., a 73-year-old laborer, was referred to the Medical Service for the treatment of decompensated heart disease. On admission there was found to be marked enlargement of the heart, auricular fibrillation, pulmonary congestion and peripheral edema. The blood pressure was 200/110. There was also a football-sized, right, direct hernia, which was difficult to reduce. Two weeks after admission, improved by rest and digitalization, the patient requested that the hernia be repaired, since it had always been an encumbrance and no truss had ever kept it reduced. After some deliberation operation was carried out under local anesthesia. At the time of operation, fibrillation, pulmo-

*From the Surgical Service of the Peter Bent Brigham Hospital, Boston.

[†]Assistant in surgery, Harvard Medical School; junior associate in surgery, Peter Bent Brigham Hospital, Boston.

nary congestion and peripheral edema were still present. The procedure required more than 2 hours. Fine silk sutures were used throughout. The postoperative course was entirely uneventful save for mild disorientation for about 24 hours. The patient was discharged improved

One hundred and twenty five chronic or degenerative illnesses were distributed among the remaining 85 patients. These are listed in Table 1, together with the postoperative complications that

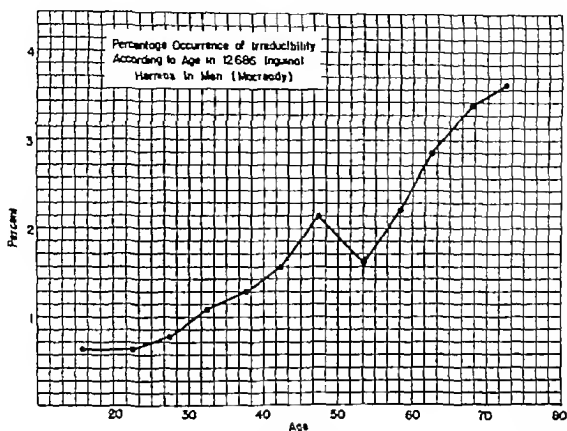

FIGURE 2.

Chart constructed from figures given by Macready (*A Treatise on Rup-tures*, 442 pp Philadelphia Blakiston Son & Co 1893)

20 days after operation. Death due to cardiac failure occurred suddenly 6 months later. There was no recurrence of the hernia.

Any consideration of surgery in the aged must involve a careful evaluation of chronic or degen-

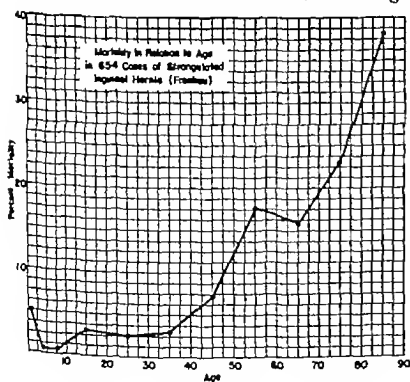

FIGURE 3.

erative disease other than that for which operation is performed. Only 15 of the 100 patients studied were found to be entirely free from other disease.

could reasonably be attributed to them. The great majority could be classified among benign prostatic hypertrophy (or a history of previous prostatectomy), cardiovascular degeneration and chronic

TABLE 1 Relation of Concomitant Disease to Postoperative Complications

| CONCOMITANT DISEASE | NO. OF CASES | REFERABLE POSTOPERATIVE COMPLICATIONS | |
|--|--------------|---------------------------------------|-------------|
| | | NO. OF CASES | PERCENT AGE |
| Benign prostatic hypertrophy (or previous prostatectomy) | 40 | 3 | 8 |
| Cardiovascular degeneration | 26 | 3 | 11 |
| Chronic pulmonary disease | 23 | 2 | 9 |
| Miscellaneous | 36 | 9 | 25 |

pulmonary disease, all with relatively few referable postoperative complications. Included in the 36 cases of miscellaneous disease are sixteen diseases ranging from diabetes mellitus to hemochromatosis. Nine, or 25 per cent, of these patients developed referable postoperative complications.

Local novocain was the most frequently employed anesthetic in the series, and had the lowest incidence of postoperative complications. Nitrous oxide and oxygen, ether and spinal novocain followed in order of usage (Table 2). There was no correlation between the use of novocain and wound infections, possibly because nerve blocking after the method of Cushing² was almost invia-

aged patient when carried out under novocain nerve-block anesthesia, with the minimum of pre-operative medication and with fine silk as the suture material

CHRONIC BRUCELLOSIS*

1 The Incidence of Chronic Undulant Fever in Rhode Island

CECIL C DUSTIN, M.D.,† AND HENRY L C WEYLER, M.D.‡

PROVIDENCE, RHODE ISLAND

A STUDY of over 4000 individuals in Rhode Island during the past four and a half years has revealed in 441, or about 10 per cent, clinical and laboratory evidence supporting a diagnosis of chronic brucellosis. Seven hundred and ninety-nine (18 per cent) had positive reactions to one of the following three tests: intradermal, intramuscular, agglutination. The 441 who had clinical evidence of chronic brucellosis showed positive reactions to at least two of these tests.

A positive reaction to any of the tests used in making a diagnosis of undulant fever should make one suspicious of its presence. According to Evans, Robinson and Baumgartner,¹ a positive agglutination test is more reliable than a positive skin reaction. They found the opsonocytophagic reaction to be the least reliable of the specific tests, of which the intracutaneous test is probably the least standardized. Various antigens have been used, such as heat-killed bacteria, a filtrate of an extract of the ground bacterial cells, a filtrate of old cultures and a lipid-free antigen. Moreover, the amount and dilutions used for testing have not been uniform. In spite of these differences, the percentage of positive reactions has been high in the skin tests, as well as in the other tests used in various sections of this country. It is generally recognized that the greater and more frequent the contact which man has with infected animals, the greater the percentage of positive reactions, no matter which of the tests is used.

Goldstein, Fox and Carpenter² found that 10.1 per cent of 332 unselected hospital patients gave positive intradermal reactions. They used a clear

culture filtrate containing 13.3 mg of nitrogen per 100 cc, injecting 0.1 cc of a 1:100 dilution. Angle, Algie, Baumgartner and Lunsford³ obtained positive reactions in 9 per cent of 712 school children. They used Huddleson's "brucellergin" for the intradermal tests.^{3,4} They found, moreover, an increasing percentage of positive cutaneous reactors in successive age groups up to early adulthood. The lowest percentage of positive reactions was found in negro children. Levin⁵ tested 365 individuals, and found that of the 27 (7 per cent) having positive skin reactions, 15 showed clinical evidence of chronic brucellosis. He used a fat-free ground bacterial suspension containing 0.004 mg dry bacterial protein per 0.2 cc. Meyer and Geiger⁶ found cutaneous reactions in 10 per cent of a group of medical students and in 60 per cent of a group of veterinarians. Gersh and Mugrage⁷ submitted 491 hospital patients to the skin test and obtained positive reactions in 12 per cent. This was a much higher percentage than he found in the agglutination test, which was positive in only 1.2 per cent of 5000 cases.

There have been a number of reports on agglutination tests for the presence of brucella antibodies. A few of these are given to indicate the wide variation. Hunt and Noll⁸ found that 8.9 per cent were positive in 1000 samples of blood serum tested. They considered reactions below a 1:80 dilution without significance. Giordano and Ableson⁹ carried out agglutination tests on 1100 human serums which had been submitted for Widal or Wassermann tests or for chemical analysis, and found that 5.7 per cent had positive tests. Dolman and Hudson¹⁰ tested 5068 specimens of

nary congestion and peripheral edema were still present. The procedure required more than 2 hours. Fine silk sutures were used throughout. The postoperative course was entirely uneventful save for mild disorientation for about 24 hours. The patient was discharged, improved.

One hundred and twenty five chronic or degenerative illnesses were distributed among the remaining 85 patients. These are listed in Table 1, together with the postoperative complications that

pulmonary disease, all with relatively few referable postoperative complications. Included in the 36 cases of miscellaneous disease are sixteen diseases ranging from diabetes mellitus to hemochromatosis. Nine, or 25 per cent, of these patients developed referable postoperative complications.

Local novocain was the most frequently employed anesthetic in the series, and had the lowest incidence of postoperative complications. Nitrous oxide and oxygen ether and spinal novocain followed in order of usage (Table 2). There was no correlation between the use of novocain and wound infections, possibly because nerve blocking, after the method of Cushing² was not

toma. Autogenous fascia was used eight times in the repair of a hernia. One of these patients developed a thrombophlebitis.

In 2 cases, herniorrhaphy was carried out at the same time as perineal prostatectomy. One of these patients developed ecchymosis of the scrotum, and the other was irrational for the first twenty-four hours after operation. In 2 other cases herniorrhaphy was carried out during convalescence from prostatectomy, and 1 patient's hernia was repaired while he was being prepared for prostatectomy. None of these patients developed complications. Hemorrhoidectomy was performed immediately after herniorrhaphy in 1 case without

operated in the remaining 21 patients whose hernias were repaired at a single operation.

Excision of a hydrocele was combined with herniorrhaphy in 10 cases. Five of these patients developed wound complications—2 suppurative and 3 nonsuppurative. In both the former and 2 of the latter, catgut sutures were used throughout. In no operation in which fine silk was used was there a suppurative complication. In fact, of all the factors associated with the operation which might contribute to postoperative wound compli-

*Two patients had silk sutures on one side and catgut on the other.

event. It would seem unwise to combine herniorrhaphy with other major surgery, but at the same time there does not appear to be any advantage in operating on multiple hernias in stages. In fact, the dangers of prolonged recumbency, notably bronchopneumonia and thromboembolic disease, may outweigh the possible advantages of avoiding a prolonged operation. Nine of the 30 patients who had bilateral hernias, or combinations of hernias requiring operation on both groins, were operated on in two stages. Five, or 55 per cent, developed complications, 1 terminating fatally. Exactly the same percentage of complications devel-

related to the operation, it seemed wisest to include everything that disturbed the postoperative course in the slightest as being at least potentially dangerous in this age group. No correlation could be discovered between complications and operating time, the type of operation or the experience of the surgeon. The low incidence of pulmonary complications is probably fortuitous, since the average time spent in bed after operation was fourteen days. However, activity in bed was encouraged and breathing exercises were frequently employed.

The frequency of postoperative disorientation

appears to be related to preoperative medication. Of the 7 patients exhibiting this complication, 5 were operated on under local or spinal novocain, reinforced with relatively large doses of morphine, scopolamine or barbiturates.

Contact was made with 79 patients one year or more after operation. Twenty four of these replied by mail that they had been benefited by operation and had no evidence of recurrence. This was regarded as highly unlikely, if not impossible, and therefore only the remaining 55 patients who were examined one year or more after operation by a member of the staff of the hospital were considered. There were eight recurrences (11 per cent) among the 76 hernias repaired in these patients, four direct and four indirect.

No correlation could be found between the incidence of recurrence and concomitant disease, the experience of the surgeon, the anesthetic or the age, weight or blood pressure of the patient. No recurrences developed among the patients who were operated on for incarceration or strangulation. More than twice as many recurrences occurred among the patients who developed postoperative complications (17 per cent) as among those whose convalescence was uneventful (7 per cent). Neither of the patients whose wounds became septic suffered a recurrence. The type of operation was apparently a factor in recurrence (Table 5). However, the radical Halsted proce-

20 patients of seventy or older with 1 death. Dulin⁵ concludes that the repair of inguinal hernia in the aged is not only relatively dangerous but unsatisfactory. He reports 301 patients sixty or older with a recurrence rate of 20.5 per cent and a mortality rate of 3.8 per cent. He found that 80 per cent of wounds became infected when local anesthesia was used, and 23 per cent when spinal anesthesia or nitrous oxide and oxygen was used. Sutures of No. 3 and No. 2 chromic catgut were used exclusively in this series.

The great importance of the suture material in relation to complications and recurrence after herniorrhaphy is now generally recognized. The recent experimental work of Meloney,⁶ Shambaugh and Dunphy,⁷ and others has been amply confirmed by such clinical studies as those of Parsons,⁸ Beckman and Sullivan,⁹ Burdick, Gillespie and Higinbotham¹⁰ and Shambaugh.¹¹ In every case the teachings of Halsted¹² have been vindicated, and fine silk has been found to be from every point of view the best suture material. The present study, although based on a relatively small number of cases, provides further evidence in support of this teaching, and demonstrates that inguinal herniorrhaphy, whether elective or imperative, is a reasonably safe and satisfactory procedure for the aged patient.

SUMMARY

One hundred consecutive cases were studied in which operation for inguinal hernia was carried out at the age of sixty-five or older. In 10 cases the operation was an imperative or emergency procedure, in the remaining 90 it was elective.

The operative mortality of the series was 1 per cent. One and seven tenths per cent of the one hundred and thirty incisions became infected. Ten and eight-tenths per cent of seventy six hernias examined one year or more after operation recurred.

Nearly three times as many wound complications and recurrences occurred when catgut was used as when fine silk was employed.

The same incidence of complications followed the repair of multiple hernias in stages as in a single operation.

Novocain nerve-block anesthesia was followed by the lowest incidence of postoperative complications. The Bassini type of operation was the most satisfactory from the point of view of recurrence. There was no correlation between the incidence of complications or recurrence and operating time, the experience of the surgeon, concomitant disease and the age, weight or blood pressure of the patient.

Inguinal herniorrhaphy, whether elective or imperative, is a safe and satisfactory procedure for the

dures with subcutaneous transplantation of the cord was employed most frequently in patients with poor musculature and fascia, and therefore with a greater possibility of recurrence.

The most important single factor in recurrence appeared to be the suture material. The percentage of recurrence was nearly three times as great when catgut was used as when fine silk was employed (Table 3).

COMMENT

Grace and Johnson³ have pointed out that there is very little accurate information available concerning the results of herniorrhaphy in patients over fifty. They report 1032 patients with an incidence of infection of 4.95 per cent and a recurrence rate of 26.6 per cent. Brooks⁴ has reported

aged patient when carried out under novocain nerve-block anesthesia, with the minimum of pre-operative medication and with fine silk as the suture material

CHRONIC BRUCELLOSIS*

1 The Incidence of Chronic Undulant Fever in Rhode Island

CECIL C DUSTIN, M.D.,† AND HENRY L C WEYLER, M.D.‡

PROVIDENCE, RHODE ISLAND

A STUDY of over 4000 individuals in Rhode Island during the past four and a half years has revealed in 441, or about 10 per cent, clinical and laboratory evidence supporting a diagnosis of chronic brucellosis§. Seven hundred and ninety-nine (18 per cent) had positive reactions to one of the following three tests—intradermal, intramuscular, agglutination. The 441 who had clinical evidence of chronic brucellosis showed positive reactions to at least two of these tests.

A positive reaction to any of the tests used in making a diagnosis of undulant fever should make one suspicious of its presence. According to Evans, Robinson and Baumgartner,¹ a positive agglutination test is more reliable than a positive skin reaction. They found the opsonocytaphagic reaction to be the least reliable of the specific tests, of which the intracutaneous test is probably the least standardized. Various antigens have been used, such as heat-killed bacteria, a filtrate of an extract of the ground bacterial cells, a filtrate of old cultures and a lipid-free antigen. Moreover, the amount and dilutions used for testing have not been uniform. In spite of these differences, the percentage of positive reactions has been high in the skin tests, as well as in the other tests used in various sections of this country. It is generally recognized that the greater and more frequent the contact which man has with infected animals, the greater the percentage of positive reactions, no matter which of the tests is used.

Goldstein, Fox and Carpenter² found that 10.1 per cent of 332 unselected hospital patients gave positive intradermal reactions. They used a clear

culture filtrate containing 13.3 mg of nitrogen per 100 cc, injecting 0.1 cc of a 1:100 dilution. Angle, Algie, Baumgartner and Lunsford³ obtained positive reactions in 9 per cent of 7122 school children. They used Huddleson's "brucellergen" for the intradermal tests.^{3,4} They found, moreover, an increasing percentage of positive cutaneous reactors in successive age groups up to early adulthood. The lowest percentage of positive reactions was found in negro children. Levin⁵ tested 365 individuals, and found that of the 27 (7 per cent) having positive skin reactions, 15 showed clinical evidence of chronic brucellosis. He used a fat-free ground bacterial suspension containing 0.004 mg dry bacterial protein per 0.2 cc. Meyer and Geiger⁶ found cutaneous reactions in 10 per cent of a group of medical students and in 60 per cent of a group of veterinarians. Gersh and Mugrage⁷ submitted 491 hospital patients to the skin test and obtained positive reactions in 12 per cent. This was a much higher percentage than he found in the agglutination test, which was positive in only 1.2 per cent of 5000 cases.

There have been a number of reports on agglutination tests for the presence of brucella antibodies. A few of these are given to indicate the wide variation. Hunt and Noll⁸ found that 8.9 per cent were positive in 1000 samples of blood serum tested. They considered reactions below a 1:80 dilution without significance. Giordano and Ableson⁹ carried out agglutination tests on 1100 human serums which had been submitted for Widal or Wassermann tests or for chemical analysis, and found that 5.7 per cent had positive tests. Dolman and Hudson¹⁰ tested 5068 specimens of

*This is the first of a series of articles on chronic brucellosis.

†Visiting physician, Rhode Island Hospital, Providence.

‡Assistant visiting physician, Rhode Island Hospital, Providence.

§The clinical findings in these cases will be discussed in a later paper.

blood and obtained 4.5 per cent positive agglutinations.

At the Rhode Island Hospital during 1937 and 1938, 372 serums sent to the laboratory for a Widal test were also tested for brucella agglutination, using a commercial antigen. Of this group 12 per cent had positive reactions in dilutions of 1:40 or bigger, and 9 per cent in dilutions of 1:80 or higher. However, only 78 cases of acute undulant fever have been reported in Rhode Island for the decade ending January, 1939.

Rhode Island is primarily an industrial state, only 1.3 per cent of its population being engaged in agriculture, as compared with 10.6 per cent in Vermont.¹¹ During the latter part of 1937, 62 per cent of the Rhode Island milk supply was produced at home, 20 per cent came from Connecticut, 16 per cent from Massachusetts and 2 per cent from Vermont.¹² Of the total milk supply available for sale in Rhode Island 76 per cent is produced for pasteurization and 24 per cent for sale as raw milk.¹³ In Providence in 1937, 92 per cent of the total milk sold was pasteurized and 8 per cent was raw. In Newport the percentage of pasteurized milk is even higher.¹⁴ All the milk imported from Vermont is pasteurized either at the source or within Rhode Island.

From May, 1936, to May, 1937, approximately 10 per cent of the cattle in Rhode Island were tested for Bang's disease. Approximately 10 per cent of those tested proved to be positive; an additional 10 per cent were suspicious.¹⁵ Because of the unusual characteristics of the brucella organisms and the ease with which all food products, including meats, eggs, butter, ice-cream, cheese, milk, fruits and vegetables may become contaminated, it is evident that milk should not be regarded as the commonest source of infection.^{16, 17} Except in rare cases where mastitis is present the organisms are not found in the milk even when the cows are known to be infected. The milk may, of course, be contaminated by careless handling. Brucella organisms have been isolated from hens, and all domestic animals have been shown to be carriers of this disease.¹⁸⁻¹⁷ It has also been found that the organisms may survive for a year or more in manure stored under ordinary New England farm conditions. There is no evidence, however, that they multiply except in infected animals. The prevalence of the brucella organism suggests that the infection may be almost universal in a given community and that only certain individuals become chronically ill.

Within the last two years the literature has been rich in articles dealing with the incidence, diagnostic procedures and treatment of various forms of infection with the brucella organism in

man. At the present time the nomenclature is rather confusing because the term "undulant fever" represents only those infections showing the characteristic temperature changes. In this country the typical undulating type of temperature in the acute infection is rarely seen. So far as our own experience is concerned, only 1 case showing the typical undulating fever has been encountered.

The clinical picture and course of the usual acute form of this infection is familiar to all and has been adequately described. There is, however, a mass of evidence supporting the contention that there is a definite chronic form of this infection in human beings, to which the term "brucellosis" may well be applied.

Nearly all the recent studies dealing with the diagnosis and incidence of chronic brucella infections have been carried on in groups of university students or school children or the inhabitants of various institutions that include the chronically ill in the later decades of life. In general, the incidence of this disease, in all groups studied, is in the neighborhood of 10 per cent. This figure is about that found in our group of private patients. It also holds true in our studies made of groups from outpatient departments, the medical wards, almshouse inmates and patients in a hospital for chronic mental diseases, where the same technique was used.

The present study of private cases deals with the people encountered in a practice limited to internal medicine, and obviously with a group of patients who voluntarily seek medical aid. The general relation between chronic brucellosis and personal allergy is significant. Of the private cases studied, 92 per cent had a history of allergy and all had a history of allergy in their immediate families. Those people showing active symptoms of the chronic infection are probably suffering from a hypersensitivity to *Brucella abortus*. The clinical behavior of these cases, when under treatment, indicates an allergic state rather than a lowered resistance. The reactions to varying concentrations of antigen solutions used in the intradermal test are consistent with a hypersensitive state. Individuals highly sensitive may react negatively to a strong antigen solution, but show a strongly positive intradermal reaction if very dilute solutions are used. This fact has also been observed by us in the intradermal reactions to solutions of various drugs, chemicals, alkaloids and bacterial proteins. Possibly this explains a part, at least, of the often reported discrepancies between intradermal and serum agglutination tests. The patients' chief complaints many times, have no apparent relation to this infection, but it must be remembered that as a group they are not well people. It is quite to be expected

that figures derived from such a group would not agree entirely with those obtained from groups of students or from studies made on blood sent to the laboratory for the Wassermann or Widal test

In this study, besides the clinical evidence, three distinct tests were used in establishing the diagnosis: the intradermal test, the serum agglutination test and the intramuscular test

The serum agglutination test, carried out on all cases regardless of history or clinical findings, was essentially that described by Carpenter, Boak and Chapman,¹⁶ with the following alterations: depression slides with sealed cover glasses were used instead of tubes. We found the wire loop for preparing the various dilutions, if handled with reasonable care, more rapid than and practically as satisfactory as the capillary pipettes or the rheometer. Sterile saline solution (0.85 per cent) was used for diluting fluid. All the glassware was chemically clean and sterile. The preparations were sealed with heavy oil, care being taken to prevent any contamination of the preparation. The work was carried out as rapidly as possible without interfering with accuracy, in order to prevent evaporation of the solutions. We found this necessary, for in tests carried out in overheated rooms or with opened windows and strong drafts, or with slow technic, evaporation sometimes altered the results in the more dilute preparations by over 25 per cent by the time the readings were made. Because of this no reliance was placed on any open-slide method.

With a little experience the depression slide technic proved to be a timesaver. A larger number of tests can be incubated in a much smaller space than is necessary for the tube technic. Instead of a series of dilutions from 1:15 to 1:405, the dilutions were carried on to about 1:10,000. Also, a series of slides was prepared in a similar manner but with the antigen diluted in one series to 1:10 and in another to 1:100, the serum dilutions being as in the first series. Also, a series was prepared using similar dilutions of serum and antigen. Thus all combinations of various dilutions of both antigen and serum are represented. Occasionally agglutination occurs only in higher dilutions of both antigen and serum. The result of a test varies depending on the time in the cycle of antibody production at which the sample is taken. We found many individuals showing a rather cyclic rise and fall in the serum titer. There may be in the host a variation in the degree of absorption of antigenic substances, or the response of the individual may be the variable factor. When this fact was established, a system of taking repeated specimens at two-week intervals was adopted, and if three negatives were obtained, two more

specimens were taken at three-week intervals. In some cases, positive tests were obtained only in this manner. Dilutions of 1:40 or higher were considered positive if one of the other tests was also positive.

The solution used for the intradermal test was a very dilute, fat-free aqueous solution derived from ground, heat-killed *Brucella abortus* (bovine, caprine and swine in equal proportions). The three dilutions used represented a protein solution equivalent to suspensions of 250,000, 25,000, and 2,500 bacteria per cubic centimeter. Only 0.02 cc. of each dilution was injected intradermally, thus the doses used represented, in protein, the equivalent of 5,000, 500 and 50 bacteria respectively. In a few of the obviously severe cases, even more dilute solutions were used. The amount used was minute, but in very sensitive cases small areas of superficial slough occurred even with the smallest doses. Often pigmented areas remained for six or more months. Any discolored area 5 mm. or more in diameter remaining after sixty hours was considered a positive reaction. The severity of the reaction did not seem to have any bearing on the serum titer, but did vary closely with the degree of sensitivity as shown by the clinical findings and reaction to therapeutic antigen. The intradermal reaction is a valuable guide in determining the proper dosage of therapeutic antigen.

The positive intramuscular test is determined by a rise in temperature to 100°F or more during the forty-eight-hour period following the intramuscular injection of 0.5 cc. of antigen solution. The material used was equivalent to 2,500,000 bacteria per cubic centimeter. The normal person shows no rise in temperature when many times the indicated dose is injected. It is unusual to find a noninfected person showing more than the slightest rise in temperature after the intramuscular injection of as much as 1 cc. of the commercial vaccine, concentrated to contain 2,000,000,000 bacteria per cubic centimeter.

Agglutination tests were carried out before any antigen was used intradermally or intramuscularly. It was found that intradermal tests made with the dilute antigen did not appreciably increase the serum titer. Strong concentrations of antigen and strong suspensions of the vaccine increased the titer somewhat, but for a period of only a few weeks. The titer is influenced by intramuscular tests, particularly if a strong antigen solution or heavy vaccine suspensions are used. The intramuscular test was depended on mainly when the agreement of the other tests was open to question. It always agreed with a negative intradermal test. In our hands the intramuscular test proved

very valuable, but the reactions sometimes induced were disturbing to the patient.

By this method of investigation any patient presenting clinical evidence as well as showing two positive tests of the three available was considered to have chronic brucellosis. Certain complaints and physical findings were always present, or had recently been present, in all cases showing the required positive laboratory tests.

Of our 441 positive cases, more than 50 per cent have been under observation for from two months to four and a half years. About 90 per cent of these patients followed the advised treatment. Less than 10 per cent either have been living at a distance or refused to believe that such a condition existed. This disbelief seems to arise from a dearth of available information on this subject.

CONCLUSIONS

We believe that chronic brucellosis is prevalent in southern New England. It is of economic importance because it is often a cause of disability sufficient to prevent normal physical activity among working people.

Many so-called neurasthenics are suffering from this condition. Its clinical aspect is varied, and puzzling to the patient and physician alike. It does not follow the usual course of chronic infection so much as it does that of a chronic allergic state. If we consider this condition from a standpoint of allergy, a more reasonable system of treatment would be desensitization.

Practical, simple and quite reliable methods of diagnosis are available and should be more generally utilized.

The general incrimination of raw milk as the chief source of brucellosis is subject to criticism, as the contamination through other food products and through other channels is of equal importance.

A plea is entered for more serious consideration of the victims of chronic brucellosis and for a more careful study of the disease.

REPORT ON MEDICAL PROGRESS

ALLERGIC DISEASES

With Special Reference to Histamine and Acetylcholine

FRANCIS M. RACKEMANN, M.D.*

BOSTON

WHY should histamine be regarded as the active end substance which results from many kinds of reactions and is, therefore, the immediate cause of asthma? The question was asked in the review¹ of last year, and demands a more detailed answer than the one there given.

In 1910, Barger and Dale² studied the poisons of ergot, and isolated beta iminazolyethylamine as one of them. They called it "histamine." They showed that histamine could cause contraction of the isolated uterus of the guinea pig when added to the bath in which the strip was suspended, and a marked fall in the cat's blood pressure when injected intravenously into the intact animal. These two effects are so characteristic that they are used today as measures of the concentration of histamine in unknown solutions. When histamine in tiny doses is injected intravenously into a guinea pig, severe bronchospasm develops at once, and the animal usually succumbs with signs and symptoms which are quite like those of anaphylactic shock. When histamine, even in high dilution, is applied to a scratch in the skin of animals and man, an immediate reaction with urticarial wheal and surrounding erythema develops within a few minutes.

On the basis of its physiologic effects, there is ample reason to suspect histamine as the ultimate active agent in anaphylactic and allergic reactions, and the theory that the substance is released from normal cells following injury by trauma or by a specific antigen-antibody reaction taking place in the cell surface is not unreasonable. However, as Best and McHenry³ ask, "Can such a potent substance be present in the active state in living tissue, and if so, what holds it in its place?" It is easy to show that extracts of many different tissues, as well as of such substances as ergot, yeast, peptone, casein and pituitary extract, have a depressor action on the cat's blood pressure or stimulate the guinea pig's intestinal strip, but it is not so easy to be sure that the activity of the extract depends on histamine. Fortunately it has been possible in many cases to identify the histamine by chemical means as the picrate. The first identification was the isolation of histamine from in-

testinal mucosa by Barger and Dale⁴ in 1911. Some years later, Abel and Kubota⁵ isolated histamine dipicrate from dried pituitary material, and so claimed that the uterus-stimulating factor in pituitary extract was nothing more or less than histamine. Now, however, it is recognized that pituitrin has a more specific action that does not include the flush, the low blood pressure and the vasodilatation produced by histamine.

Meantime, it was known from chemical studies that histidine is largely distributed through the body, and that histamine could be made from it by processes of oxidation as well as by the action of bacteria. This last possibility made it necessary to study tissues that were fresh and uncontaminated. It was not until 1927 that Best, Dale, Dudley and Thorpe⁶ prepared histamine in crystalline form from the normal liver, lung, spleen and muscle of the ox.

The properties of histamine are interesting. It is very poisonous, the quantities needed to kill by intravenous injection are extremely small, although the lethal dose varies among different animals. The guinea pig is killed by 0.30 mg per kilogram of body weight, while the rat is much more resistant, requiring 300 mg per kilogram for a fatal result. Weiss, Robb and Blumgart⁷ used the facial flush (capillary dilatation) that follows the intravenous injection of histamine into man as a measure of the velocity of blood flow, and found that the safe intravenous dose for man was not larger than 0.001 mg per kilogram of body weight, or an average total dose of 0.07 mg. Actually the authors gave 0.35 cc of a 1/5000 dilution of ergamine acid phosphate. Pertinent here was their observation that all patients with emphysema, bronchitis and asthma showed temporarily increased dyspnea with the symptom, asthma, after the administration of histamine. The patients were susceptible to the drug. Furthermore, it is known that normal persons and also asthmatic patients regularly show an immediate local reaction when a drop of 1/10,000 dilution (about 0.02 mg) of histamine is applied to a scratch in the skin.

Histamine is stable. The method of assay, as modified by Code,⁸ begins with the removal of protein substances by boiling in the presence of

*Associate in medicine Harvard Medical School physician Massachusetts General Hospital Boston

acetic acid, the histamine remains intact in the filtrate. In this regard, histamine behaves very differently from acetylcholine.

A second constituent of normal tissues is acetylcholine. A review of this substance, including its relation to other tissue derivatives, is included in the recent book by Cannon and Rosenblueth,⁹ *Autonomic Neuroeffector Systems*. In 1906, Hunt and Taveau¹⁰ published a paper "On the Physiological Action of Certain Choline Derivatives and New Methods for Detecting Choline." They pointed out that the acetic ester of choline was extremely active as a vasodilator and depressor substance. Later, Dale¹¹ found that aside from histamine, ergot contained another very active substance, the injection of which could slow the heart rate, cause marked vasodilation and stimulate contractions of the gastrointestinal tract, the substance resembled acetylcholine. In 1921, Loewi¹² isolated the hearts of two frogs and filled them with Ringer's solution. The vagus of one was stimulated for a few minutes. The fluid in that heart was then transferred to the second heart, which thereupon reacted as if its own vagus had been stimulated. The first vagus stimulation had given rise to a chemical substance that Loewi thereupon called *Vagusstoff*. After this, other investigators found that stimulation of the parasympathetic nerves running to many different organs—the chorda tympani nerve to the salivary gland, for example—caused the appearance of a similar substance in the blood, and that this could be carried to other organs, to mimic in them the effects of parasympathetic nerve impulses. The *Vagusstoff* was identified later as acetylcholine.

Acetylcholine has two pharmacologic characteristics that distinguish it from histamine. The base choline is stable, but it is not very active physiologically. Its esters, on the other hand, are labile but they are many hundred times as active as the base choline, and it is acetylcholine which has been identified in the body cells under certain conditions and which has been studied so extensively. However, when acetylcholine is introduced artificially into the body it is destroyed almost at once on contact with animal blood or tissue. This destruction depends on an enzyme—cholinesterase—which is present in normal tissues and which acts by hydrolyzing the ester into its two original components. Loewi¹³ and others showed that this enzyme could be inactivated by heat as are other enzymes. More important, the action of the enzyme is inhibited by the drug, eserine (physostigmine), as Loewi and Navratil¹⁴ were able to demonstrate, and this protection of acetylcholine has played an important role in many

studies. The action of eserine consists in preventing the union between acetylcholine and cholinesterase. Animals and tissues that are under the influence of eserine allow the full effect of acetylcholine to be exhibited and analyzed.

The second characteristic of acetylcholine is that its action is promptly and effectively prevented by atropine. Atropine appears to stop the access of acetylcholine to the cells of smooth and cardiac muscle and of glands. In spite of the fact that acetylcholine has a normal physiological function, it may (like histamine) become a poison when injected into man and animals. In the form of a stable synthetic compound—acetyl beta methylcholine—it has been used in the treatment of man and animals with profound effects. It causes contraction of striated muscles, it slows the heart and it lowers the blood pressure by causing a dilatation of peripheral arterioles, it causes sweating, flushing and rhinorrhea, finally, it may induce bronchospasm. All these effects are quite comparable with those following the injection of histamine. Each of the substances can induce asthma in susceptible persons. The one great difference is, however, that the effects of acetyl beta methylcholine can be blocked promptly by the administration of atropine, just as they can be enhanced by treatment with physostigmine, yet neither physostigmine nor atropine has any effect on the action of histamine. The importance of this relation is shown by the following report. Kokas, Sarkady and Went¹⁵ sensitized dogs to foreign protein and then before the second shocking dose was given they treated the animals with full doses of atropine. The fact that anaphylactic shock resulted as usual from the second dose and that atropine had not blocked the reaction was, to the authors, a demonstration that the anaphylactic poison was histamine and not acetylcholine.

These previous findings are summarized here for two reasons. First, there is today among students of the allergic diseases an increasing interest in histamine, even though as yet its role cannot be demonstrated with any assurance. Second, acetylcholine, like histamine, is found as a constituent of normal tissues, from which it is released by simple mechanisms, and it has effects that are much like those of histamine. It seems quite proper to examine the possibility that this other chemical neuroeffector—acetylcholine—may be playing a significant part in these peculiar clinical conditions.

The synthetic compound acetyl beta methylcholine (Mechoyl) is stable and has been used in many experiments both on man and on animals. Villaret and his co-workers¹⁶ found that a dose of

20 to 40 mg injected subcutaneously was enough to produce an attack of asthma in each of fifteen asthmatic patients and quite regardless of the type of asthma from which the individual patient suffered. Starr, Elsom, Reisinger and Richards¹⁷ and their associates have studied the clinical effects of acetyl beta methylcholine on many patients with various conditions including, especially, paroxysmal tachycardia (to use the parasympathetic effect on the pulse rate) and Buerger's disease (to use the peripheral vasodilator effect). Included in their study is the observation of a young man with a previous history of asthma who developed a typical asthmatic attack immediately following the administration of the drug. The attack lasted for about three minutes and then subsided spontaneously. The dose is not stated.

Fraser¹⁸ has studied the clinical effects of acetyl beta methylcholine extensively. Among other experiments, he watched under the fluoroscope the introduction of Lipiodol into the trachea and bronchi of a woman who had just been given a dose of 25 mg of Mecholyl intramuscularly. A definite constriction of the smaller bronchi was observed.

Myerson¹⁹ and his associates have also worked with the same drug but so far their subjects have not included patients with asthma.

Parrot²⁰ gave a milligram of eserine salicylate to a group of fasting individuals, drew samples of blood and then tested them on eserinated leech muscle. Using the blood of normal persons, no contraction occurred,—no acetylcholine could be demonstrated,—but in the blood of asthmatics, acetylcholine was found in seven out of the eight samples studied.

An analogous experiment but performed on rabbits is reported by Wenner and Buhrmester²¹. These authors sensitized rabbits to egg white and bled them during the shock resulting from a later dose. The acetylcholine content of the extracted blood was tested by intravenous injection into atropinized cats, so as to exclude the effect of histamine, and was then applied to a strip of eserinated muscle from the back of a leech. It was found that the amount of acetylcholine in the blood of the shocked animals was equivalent to a 1:1,000,000 or 1:10,000,000 dilution of acetylcholine chloride, whereas the blood of other sensitized but unshocked animals was equivalent to about half that strength, and the blood of normal nonsensitized animals contained no measurable amount. This result is especially interesting because the original sensitized rabbits were not treated with eserine before the shock and so one can assume that if acetylcholine was produced by the shock,

the amount destroyed before the blood was drawn was larger than the amount estimated by the test.

Milhorat²² made a different approach to the problem. He studied the cholinesterase activity of the blood in 109 patients with various diseases. He added the serum to known quantities of acetylcholine, and considered the amount of acetic acid set free by the enzyme as representing the amount of acetylcholine in the specimen. Five patients with asthma were included but the results, as in the other cases, varied widely and no conclusions could be drawn.

So far there is no other report of studies on the blood content of acetylcholine in patients with asthma. The problem is difficult, partly because the quantities to be expected are infinitesimal, and more important, because this substance in contrast to histamine is very delicate and labile. Obviously, however, further studies must be made because theoretically, as Alexander²³ said in his discussion of Wenner and Buhrmester's paper, histamine does not quite fill the bill but acetylcholine does,—and I add,—except for the one fact that its effect on the cells is easily blocked by atropine.

On histamine, recent studies include the following. If histamine is responsible for such a condition as status asthmaticus, an increase of histamine in the circulating blood might be anticipated. Riesser²⁴ tried to find it, but could demonstrate no more histamine in the blood of asthmatic patients than in that of tuberculous patients. Randolph²⁵ studied the blood of several patients with severe asthma, in 2 cases within a few hours of death from the disease, but the values obtained were within the limits of those found for the blood of normal persons and for the blood of other asthmatic patients between attacks. Fiessinger, Gajdos and Panayotopoulos²⁶ studied the blood histamine in various diseases. Using the color reaction of Pauly, which is even less accurate than the biological test, they showed slightly more histamine in the blood of patients with urticaria and asthma than in that of those with cirrhosis of the liver. Code and Hester²⁷ examined the blood of 2 horses and 6 calves during anaphylactic shock and found the quantity of histamine low rather than high. In a similar experiment on dogs, Dragstedt and Mead²⁸ found that the histamine in lymph and blood varies directly with the degree of shock, and disappears as the shock subsides. Such studies are difficult because the method of determining histamine, originally devised by Barsoum and Gaddum²⁹ and modified by Code,³⁰ consists in comparing the response of an intestinal strip from a guinea pig to the unknown solution with its response to a histamine solution of standard strength, and because the values obtained are less

than 1 gamma (a thousandth of a milligram) Code has shown that 90 per cent of the blood histamine is in the white cells and particularly in the eosinophilic leukocytes. Katz³¹ observed that the leukocytes can release histamine. He immunized rabbits to egg white and added small amounts of this substance to their blood in vitro, incubating the mixture for ten minutes. When the sensitized blood had undergone shock,³² its content in histamine was from one to six times as high as in the control blood drawn and incubated without the addition of egg white.

Meantime, Rose and Browne³² have sought to find why it is that the rat is many times as resistant to histamine as is the guinea pig (I should like to think of patients with asthma as behaving toward histamine like guinea pigs, while normal persons behave like rats). Rose and Browne injected a generous dose intravenously into a series of rats, and killed the animals at intervals in order to study their organs. They found that the injected histamine collected rapidly (within fifteen minutes) in the kidneys, from which it was redistributed slowly to the other tissues. If adrenal ectomized animals were used, the rate of redistribution was much slower in accord with the general decrease in resistance of the animal. Perl³³ observed that if sterile saline solution is injected intraperitoneally into rats, or if they are fed salt for several days before the dose of histamine, their resistance to the latter is increased. One would like to correlate this finding with the favorable effect that often follows the intravenous injection of normal salt solution into patients with asthma.

There have been one or two attempts to apply the histamine theory of allergy to practical use. In 1935, Dzsinich³⁴ treated a group of asthmatic patients with injections of histamine every other day, hoping to change their allergic susceptibility (*Bereitschaft*), and claimed that 12 out of 15 patients obtained complete relief. The duration of relief and the types of cases treated are not described. I have tried the method on a few patients with asthma, but with no striking results. Incidentally it was impossible for me to increase the subcutaneous doses above the certain small quantity that produced each time a mild flushing of the skin and a definite increase of the wheeze. The tolerance for histamine could not be increased at least by this method. Farmer³⁵ has recently tested the theory of desensitization by histamine by treating animals. Guinea pigs were sensitized to horse serum and then treated with histamine injected intraperitoneally at intervals of one to three days for a period of twelve to eighteen days. Later the uterine strips were suspended in the Dale bath and tested with increasing doses of horse

serum. Farmer found that the strip from the histamine-treated animals—both sensitized and normal—required larger concentrations of horse serum to produce contraction than did the strips from the animals not treated with histamine. In another paper, Farmer³⁶ reports that the feeding of histamine by mouth could also diminish the reaction of the sensitized uterine strip.

Histaminase has a current vogue. In 1930, Best and McHenry³⁷ tried to discover why the effects of histamine, whether injected intravenously or subcutaneously, were so transient. From normal dogs, they took 20-gm samples of various tissues and suspended each in 100 cc. of salt solution, adjusting the mixture to pH 7. Two samples of each kind of tissue were studied. Forty milligrams of histamine was added to one sample without other treatment, and to the other after boiling. The pairs were incubated at 37°C. for seventy-two hours, after which histamine determinations showed 36 mg still present in the heated material, but only 0.3 mg in the unheated. This experiment demonstrated that 20 gm. of moist tissue—in this case, kidney—could destroy almost 40 mg of histamine. Later a stable powder containing the histaminase was made by extracting fresh tissue with acetone and ether and rapidly drying the residue before a fan. They found that under favorable conditions, 200 mg of powder will inactivate 2 mg of histamine in twenty-four hours. However, the activity varies for different organs, the kidney and the intestine showing activities many times as great as those of other organs. Clinical interest in histaminase has been aroused by the report of Foshay and Hagebusch³⁸ that histaminase given by mouth in the form of tablets each containing 5 "histamine-detoxifying" units (three to fifteen tablets a day) or intramuscularly in ampules each containing 1 unit (up to four ampules a day) relieves serum disease.

Laymon and Cumming³⁹ treated 17 cases of urticaria with the tablets and claimed a cure in 10. In atopic dermatitis, however, no beneficial results were obtained in 8 cases. To interpret such findings is difficult. The clinical conditions are always extremely variable, and hard to control.

Experimenting on guinea pigs, Karady and Browne⁴⁰ used the ampules containing histaminase, injecting the contents intravenously fifteen minutes before an otherwise fatal intra abdominal dose of histamine. The animals survived. Furthermore, similar treatment protected them against anaphylactic shock. That these results did not depend on some nonspecific effect of the alarm reaction in guinea pigs, as described by the same authors,⁴¹ is attested by the fact that when the histaminase was inactivated at 56°C. for an hour

before being injected all its protective power was lost. As the authors comment, the time element in these experiments is important. In the test tube, destruction of histamine by the ferment requires between forty-eight and seventy-two hours, as Best and McHenry³⁷ showed. In the living animal, however, protection occurs in a few minutes. In my laboratory, the fresh organs of rats and of guinea pigs have been ground finely and let stand for periods of several minutes to several hours in salt solution containing various small concentrations of histamine, but so far no evidence of neutralization has been obtained when the mixtures are tested on the human skin and the reaction is compared with that of control solutions.

The discrepancy between the experiments made in the test tube and those made in the living animal is hard to explain. Still other observations are hard to fit into the picture as a whole. By the proper use of a galvanic current Abramson and Ochs⁴² were able to drive histamine into the intact skin so that an immediate wheal resulted by electrophoresis. Then Abramson and Engel⁴³ found that by reversing the polarity the histamine could be drawn out and identified by reintroduction into a new area of skin. Later the method was applied to skin tests with ragweed pollen in sensitive patients. By electrophoresis typical allergic wheals could be produced, but no histamine could be drawn out when the poles were changed. In preliminary experiments, Sulzberger⁴⁴ has mixed the enzyme histaminase with histamine and with various allergens, testing the mixtures on the skin of his sensitive patients, but so far he has been unable to demonstrate any neutralization—in the test tube.

DISCUSSION

There is evidence that histamine and acetylcholine may each be concerned with clinical allergy. So far, however, this evidence consists chiefly in the striking effects that occur when these substances are injected into animals and man. Each substance is quite capable of producing a clinical picture comparable to what is recognized as asthma, and further, each can be identified as a constituent of normal tissue. It is not surprising that there has developed a theory that one or the other is the end product resulting from the activity of a wide variety of exciting causes.

The method by which these two intracellular substances are released is interesting. Histamine appears after mechanical or toxic injury to the surface of the cell. Acetylcholine results from stimulation of the cell by nerves. The pathologic picture of asthma depends on the overactivity

of the bronchial glands which pour out the mucoid secretion which gives rise to the intrabronchial plugs of tough rubbery consistence so common in asthma. If this were a nervous effect would one not expect other evidence of cholinergic activity in the body as a whole? Slow pulse, low blood pressure, diarrhea, colitis and perhaps peptic ulcer are not common in asthma, and the evidence of cholinergic activity is slight. The theory of direct injury to the bronchial wall by the allergic reaction resulting from the inhalation of the specific dust substance is more tenable, but one must also explain the development of asthma after the ingestion of specific foods or the subcutaneous injection of foreign substances which can reach the bronchi only through the blood stream. This, however, is possible and on the whole the theory of the release of histamine by injury is more acceptable than the release of acetylcholine by nerve stimulation. Moreover, the lack of relief of asthma by atropine helps to exclude acetylcholine.

Whether one must assume that the patient with asthma behaves toward either acetylcholine or histamine in a manner different from the normal person is a proper question. That the substances increase in the blood during anaphylactic shock or during an attack of asthma is suggested by some experiments but not by all. A more probable explanation is that the patient with asthma reacts to similar quantities in a manner different from the normal person, and it is possible that an approach to this theory will be found later. The suggestion that histaminase may be effective in the treatment of asthma and allied conditions requires much more study, and one must not overlook the apparent vast difference in the time factor between neutralization *in vitro* and *in vivo*. In treatment, histaminase needs much wider trial before one can say that it is of value. Serum disease, hives, asthma and hay fever are prone to occur in attacks which may come and go suddenly. The cause of the attack as well as the cause of the recovery from it may, in a given case, depend on any one of a number of possible factors. The situation is always complicated, and observations in these diseases are always hard to control. New observations must be made, but their results must be interpreted with the greatest caution.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26161

PRESENTATION OF CASE

A twenty-five-year-old unemployed single man entered the hospital complaining of "soreness" in both sides of the abdomen for the previous five days.

Ten years before admission he was told at another hospital that his spleen was enlarged and he was advised to have it removed. His father would not consent to this. He had visited the Out Patient Department of this hospital for some incidental complaint that he did not remember. Since that time he had noticed pigmented spots on his legs, which he attributed to mosquito bites. Five years before admission the family noticed that his abdomen was becoming progressively larger. At the same time the patient noticed that the gums bled easily when he brushed his teeth or when he had teeth extracted. The tendency had improved in recent years. About a year before admission the color of the skin became darker, especially over the face. Five months before admission the right ankle became swollen and tender, without preceding trauma. X-ray films were negative. The ankle remained swollen and tender for about a month. Two and a half months before admission he had worked on a PWA project for two weeks, clearing brush, but this had to be discontinued because the ankle bothered him. He again went to the local hospital, and four more x-ray films were taken, which were negative. Since then he had remained in his room and had done no further work. The ankle improved in about two weeks. Three and a half weeks before admission he again visited the hospital because of recurrence of swelling in the right ankle. He stayed there a week and was told that his teeth were bad. Two and a half weeks before admission he had a premolar tooth extracted. Following this the gum bled for two days. Three days following the extraction, nodes in the right side of the neck became swollen and his throat became sore. The throat improved in the course of a week or ten days. Four days before admission he noticed that he was becoming short of breath. He had vomited occasionally for several weeks, this became almost a daily occurrence. The abdomen had been a little sensitive for some months on the left side, but a few days before

entry had been exquisitely tender on both sides.

His mother had been born in Nova Scotia, and his father in Massachusetts. They and six siblings were living and well.

The patient had been born in Massachusetts and had always lived there. He had had mumps, whooping cough and chicken pox as a child. Sixteen years before admission he had fallen from a tree and was unconscious for two or three hours but suffered no aftereffects. The tonsils and adenoids had been removed sixteen years before admission, he had bled quite a bit following the operation.

Physical examination showed a thin, fairly well developed, acutely ill man, with a copper-colored face. The voice was moderately high pitched and childish. The skin was dry and loose, and there were brown-black, slightly depressed areas of pigmentation over the anterior surfaces of the lower extremities below the knees. The teeth were partly missing, and those remaining showed caries and pyorrhea. There were small wedge shaped fatty deposits in the sclera of each eye on both sides of the cornea. He had a thin beard over the chin but no hair elsewhere on his face. The hair on the head and in the axillary and pubic regions seemed normal. There was slight generalized adenopathy, but no nodes measured over 1 cm in diameter. There was flatness and absent sound below the third rib on the left and the fourth on the right anteriorly. Posteriorly there was flatness below the angles of the scapulas on both sides. The abdomen was very tensely held and was quite tender, especially over the left half. By percussion and palpation a mass occupying the left two thirds of the abdomen could be rather indefinitely outlined. On rectal examination a large smooth mass was felt outside the bowel rather high up. The blood pressure was 120 systolic, 70 diastolic.

The temperature was 102°F, the pulse 110, and the respirations 25.

The urine showed the slightest possible trace to a large trace of albumin on several examinations, with occasional white blood cells and occasional hyaline and rare granular casts. The stools were negative for gross and occult blood and did not show fat on staining with sudan III, before and after acidifying and heating with acetic acid. The red-cell count was 3,600,000 at entrance and gradually fell to 2,500,000. The hemoglobin was 55 per cent (Tallqvist) at entrance and fell to 45. There were from 70 to 95 per cent polymorphonuclears on many occasions, and the white cell count varied from 22,000 at entrance to 36,000. An occasional myelocyte was seen in the smears. The red blood cells showed some variation in size.

and shape and slight achromia. Platelets were normal in number at entrance but became somewhat diminished several weeks later. The oxygen capacity of the blood was 772 vol. per cent, the color index 0.80, and the volume index 0.86. There was no significant difference in the white-cell and differential counts before and twenty minutes after the administration of 0.5 cc. of adrenalin subcutaneously. The Hinton test was negative. The icteric index was 6, and the van den Bergh normal. The liver function showed 0 to 5 per cent retention in thirty minutes by the bromsulfalein test. The nonprotein nitrogen was 23 mg per 100 cc. The phenolsulfonephthalein test of renal function showed 30 per cent excretion of dye in thirty minutes. The blood cholesterol was 42 and 61 mg per 100 cc. at two determinations. The bleeding time was four minutes, and the clotting time twelve minutes, as determined in an 8-mm test tube. The Congo red test for amyloid disease was negative. The fasting blood sugar was 91 mg per 100 cc., the serum calcium 8.31 mg., the phosphorus 4.10 mg., and the serum protein 6.1 gm. No Bence Jones protein was found in the urine. The total fatty acids of the blood were 280 mg per 100 cc., an essentially normal figure.

An x-ray film of the chest was negative except for the presence of an exceedingly high diaphragm—at the level of the third ribs anteriorly and the level of the angles of the scapulas posteriorly. The bones of the skull, arms, pelvis and femur showed no definite variation from normal when examined three days after entrance. The plates of the right ankle were reported as negative. A flat abdominal plate showed generally increased density with obliteration of the normal soft tissue shadows. An intravenous pyelogram showed that the left kidney was about twice the size of the right, but this was interpreted as being due to a congenital anomaly. There was no evidence of tumor. The epiphyseal lines along both iliac crests were open. A barium enema showed a low splenic flexure but no other definite abnormality.

During his stay in the hospital he continued to run an irregularly febrile course, the temperature varying from 98 to 103°F. His weight was 102 pounds at entrance, but this gradually fell to 94 in the course of several weeks. He remained quite ill and was always tender in the left upper quadrant, although this varied in degree from day to day. He vomited about once every two days, often in the morning after breakfast. A bone marrow biopsy from the left tibia showed several focal areas of very active marrow with all the normal elements present, red blood-cell formation was very active. About one month after entry

he was given a short course of x-ray treatment (600 r, divided into three treatments of 200 r each) over the spleen, this was followed by some improvement, the size of the abdomen definitely decreasing.

During the latter part of his stay he had transient ankle edema, lasting a few days and then clearing spontaneously. He vomited more frequently during the last few weeks in the hospital. During that time it was noted on several occasions that the abdomen was quite tympanitic high in the left upper quadrant, a condition not present on admission. Five days before death, under local anesthesia, a small abdominal incision was made. Dense adhesions between the peritoneum and an underlying mass were found, and there was considerable bleeding encountered on separating these. A small V-shaped section of the underlying mass was removed, and the wound closed without drainage. Following this he continued to fail and died two and a half months after entry.

DIFFERENTIAL DIAGNOSIS

DR. SIEGFRIED J. THANNHAUSER* I should like to give the following summary of the symptoms of this twenty-five year-old man. He had been in another hospital ten years previously and since then had been continually ill and under treatment for numerous complaints of indefinite origin. Moreover, it must be believed that he was really a sick person during this period, because his physical development was not up to par and his secondary sex characteristics did not develop fully—his voice was high pitched and childish, a thin beard covered his chin, but there was no hair on any other part of his face. This kind of infantilism and sexual retardation usually indicates the gradual progression of a severe disease which, like an enemy from within, retards development.

An enlarged spleen had been observed ten years before when the patient was in the other hospital. I think there is no reason to doubt this statement, even though there is no definite mention of an enlarged spleen in the physical findings reported during the period of hospitalization here. However, the report did state that his abdomen was very tensely held and quite tender over the left half. The patient himself reported that for some months before his admission to the hospital, his abdomen had been sensitive on the left side and, later on both sides. He vomited almost every day for a few weeks. A mass occupying the left two thirds of the abdomen could be rather definitely outlined by percussion and palpation.

* Clinical professor of medicine, Tufts College Medical School; associate physician-in-chief, Joseph H. Pratt Diagnostic Hospital, Boston.

This mass was also felt by rectal examination, it was outside the bowel and rather high up. The flat abdominal x-ray plate showed a generally increased density, with obliteration of the normal soft-tissue shadows. There is no statement of an enlarged spleen. However, it is stated one month after entrance that the patient was given a short course of x-ray treatments over the spleen and that the size of the abdomen definitely decreased. But it must be re-emphasized that the history contains no exact statement about the spleen. I should nevertheless like to depend on the observation made ten years ago. Yet, something else must have developed in the patient's abdomen in addition to the enlarged spleen, because five years before admission the family had noticed that his abdomen was becoming progressively larger. The enormous mass noted in the physical findings was indefinitely outlined. The spleen alone, on the other hand, would always have very definite outlines. The smooth mass felt by rectum was certainly not the spleen, because, if so, it would not have been smooth. The intravenous pyelogram was evidently carried out to discover what other organs were involved in the large mass. It was found that the left kidney was about twice the size of the right, but this was interpreted as being of congenital origin. There was no evidence of a renal tumor. The barium enema also did not reveal a tumor, but only a low splenic flexure. In summary, I should like to say that all the search revealed nothing more than did the palpation, that is, the presence of an enormous mass with indefinite outlines. There is no statement of whether the mass moved with respiration. I should nevertheless like to assume that the mass did not belong to the kidney or to the intestines, but rather to the spleen and additional conglomerates probably present in the mesentery.

At the time when his spleen was pronounced enlarged at the first hospital, the patient also noticed pigmented spots, which persisted after their appearance. He attributed these to mosquito bites. Following up this symptom of pigmentation through the course of the disease, we find that about a year before the patient's admission here the color of the skin had become darker, especially over the face. During hospitalization, brownish-black slightly depressed areas of pigmentation were observed over the anterior surfaces of the lower legs. Small wedge-shaped, fatty deposits were noticed in the scleras of both eyes. Later, the copper-like color of the face was mentioned. The skin itself was dry and loose. In summarizing these symptoms, we have to ac-

cept the presence of a definite pigmentation, which had been increasing since the beginning of the disease.

Third, the patient had noticed before his admission to the hospital a tendency toward bleeding. This had first been observed after a tonsillectomy, and later after brushing his teeth. It was again noticed after the extraction of a tooth. With the extraction of another tooth, the gum bled for two days. Physical examination on entry revealed that his gums were in poor condition, but no bleeding spots were found.

The patient also reported that once after a tooth extraction he had swollen nodes in the neck, especially on the right side. That he had at the beginning of his hospital admission generalized adenopathy is a very important statement. It was mentioned, however, that no node was over 1 cm. in diameter. There is no subsequent mention of the adenopathy, but I believe it did not disappear, for otherwise reference would have been made to it.

The fifth feature that the patient himself had observed before admission to the hospital was swelling of the right ankle. The severe pain caused him to seek medical advice at different times, however, there were never any positive clinical or x-ray findings.

The patient's heart was normal. There were flatness and absent sounds below the third rib on the left and the fourth rib on the right anteriorly. There was flatness below the angles of the scapulas on both sides posteriorly. However, the x-ray film of the chest was negative, except for the presence of an exceedingly high diaphragm. There was no exudate, infiltrate or mediastinal shadow.

The patient did not mention that he had a fever before admission to the hospital. While at the hospital he had an irregularly febrile course, the temperature varying from 98 to 103°F. The pulse was about 110, and the respirations 25. He was very ill, and his weight fell from 102 to 94 pounds. The patient repeatedly vomited, very often in the morning.

Comparing the laboratory findings with the physical data, we note that the red-blood-cell count was 3,600,000, this gradually fell to 2,500,000. The hemoglobin dropped from 55 to 45. The white blood-cell count varied from 22,000 to 3600. The polymorphonuclears were always 95 to 97 per cent, occasionally a myelocyte was seen.

Bone-marrow biopsy revealed an active marrow with normal elements. Despite the bleeding tendency, there was no infiltration of bone marrow with a tissue that did not physiologically belong there. X-ray study of all the bones did not reveal

any abnormality in shape or structure. There was also no sign of leukemia in the bone marrow.

Chemical examination of the blood revealed two things of importance: no bilirubin, and low cholesterol and fat levels. The fact that he did not have any bilirubin excludes an increase in hemolysis or blood destruction. The low cholesterol and fat contents should be evaluated, in my opinion, as a sign of progressive disease leading to cachexia.

The liver function test with bromsulfalein was normal. The phenolsulfonephthalein test of the renal function showed 30 per cent excretion in thirty minutes. There was also an adrenalin test, but there is no report that after the test the spleen decreased in size. There was only a note that the white blood cells did not differ, before and after.

I should like to discuss four possibilities for diagnosis: splenic vein thrombosis, the so-called Banti syndrome, tumor of the adrenal gland or kidney, with invasion of the splenic vein and mesenteric metastasis, Gaucher's disease, and atypical abdominal Hodgkin's disease, with enlargement of the spleen and mesenteric lymph nodes, simulating a large tumor mass—probably reticulum-cell granuloma.

Splenic Vein Thrombosis When the patient was a youth, he had had an accident and later on developed a large spleen. While the platelets in thrombosis of the splenic vein are usually normal, the leukocytes are generally diminished in number. In this case there was leukocytosis, and only in the last few days a drop in leukocytes and platelets. The patient had never had ascites or signs of portal obstruction. The fever could be explained on the basis of the splenic vein thrombosis, and the enlargement of the kidney and the presence of large amounts of albumin by a renal vein thrombosis. However, neither the gradual development and presence of skin pigmentation nor the infantile physical appearance and retarded development are characteristic of splenic vein thrombosis. Furthermore, the outstanding feature in the later development of splenic vein thrombosis is ascites. No masses were felt in addition to the spleen.

Tumor of the Adrenal Gland or Kidney In favor of this diagnosis is the fact that an enlargement of the left kidney was noted. However, the x-ray examiner himself did not agree to the diagnosis of a tumor of the kidney. In considering a tumor of the adrenal glands, I do not know of any such tumor leading to a definite pigmentation. Neither medullary nor cortical tumors have pigmentation as a symptom. The masses felt by the rectal examination could be produced by the metastasis of such a tumor. However, the occur-

rence of all the other features, such as the bleeding tendency, pigmentation and, especially, the ten year duration of the disease, would be extremely rare in either renal or adrenal tumor. Even though nothing has been mentioned about the movement of the tumor with respiration, I should not like to believe that the kidney and spleen were confused in the examination made ten years before. Neither should I like to suggest that there was any confusion in the present examination.

Gaucher's Disease The following three features are favorable for a diagnosis of Gaucher's disease: a large spleen and general adenopathy, a bleeding tendency, and skin pigmentation on the leg and face. However, against such a diagnosis are the following findings: a normal bone marrow, normal shape of the bones, no structural deformity of the bones, the presence of granulomatous tissue in the abdomen, as evidenced by the adhesions between the peritoneum and underlying masses that were noted at the time of the abdominal incision.

Hodgkin's Disease After a discussion of these three possibilities, everything seems to draw our attention to a diagnosis of abdominal Hodgkin's disease. An initial symptom sometimes found in this disease is a tendency to bleed. An enlarged spleen is almost a constant finding. General adenopathy, which is present in Hodgkin's disease, was also observed in this case. Pigmentation of the skin and a dry skin are also found. I do not consider the pigmentation of the scleras of great importance. The intermittent fever in the last month of this case is also a feature of Hodgkin's disease. Leukocytosis in early stages but leukopenia and low platelets later are also observed. Objection may be taken to this diagnosis on the ground of the duration of the patient's illness, namely ten years. A duration of seventeen years has been observed, and I myself have a case under observation where the histological diagnosis was made ten years ago. The patient to whom I am referring is of about the same age as the one being discussed and shows exactly the same signs of infantilism. As a last indication of the granulomatous disease, I should like to call attention to the findings of the intra-abdominal biopsy, where adhesions between the peritoneum and underlying masses were found.

In conclusion, I should like to make a diagnosis of an atypical abdominal Hodgkin's disease of long duration, with pigmentation and, especially, involvement of the mesenteric nodes.

DR. FULLER ALBRIGHT There are two or three clinical features which did not come out strongly in the history. The triangular areas of fat deposit in the eyes were very striking. We thought that they were typical of Gaucher's disease, and located

fact furnishes a background for gall-bladder disease and allows a diagnosis of gallstone obstruction

Another possibility is a gradually progressing volvulus which slowly shuts off venous circulation of an intestinal loop, without producing the severe pain of a sudden, complete obstruction. Such a lesion does produce a transudation of fluid in the abdominal cavity, with tenderness, and may result in a concentrated blood indicated by an elevation of the red-cell count, it may also be accompanied by a leukocytosis. The situation calls for a decision as to whether one is going to operate as well as make a diagnosis, thus bringing up the question as to whether the patient ought to be treated conservatively by suction or a Miller-Abbott tube. I think the leukocytosis is an indication of existing or impending interference with the circulation of the small bowel and forces a decision to operate rather than to attempt deflation. I should put a slowly progressive volvulus of the small intestine as my first choice, but I should not be surprised if, in view of the urinary findings, something outside of the intestinal tract was found as a cause of the distention.

DR TRACY B MALLORY Dr Thompson, you saw this man in the Emergency Ward?

DR RICHARD H THOMPSON Yes. We believed that the findings were typical of acute small-bowel obstruction, and in view of the brief history and elevated white count, and the fact that the patient was in good condition, we decided to operate immediately. The first thing that I noted on exploring the abdomen, feeling in among dilated loops of small intestines, was a firm mass with a slightly rough surface which I thought might be a bolus of some kind in the bowel, but it soon became evident that it was a mass in the mesentery of the small intestine. There was no obstruction at the time the abdomen was opened, but there were two points in the jejunum which had undoubtedly been adherent to the mesenteric mass in such a way as to cause small-bowel obstruction by kinking. On the wall of the small intestine, which was supplied by the portion of mesentery in which the mass was found, were six or seven small firm nodules. Since I believed I was dealing with a tumor of the small intestine with metastases to the mesentery, the entire mass was resected. One or two nodules were noted distal to the resected mass. However, it seemed unwise to put the patient through a more extensive procedure, so an end-to-end closure was done and the abdomen closed.

CLINICAL DIAGNOSIS

Intestinal obstruction, acute

DR. MARKS'S DIAGNOSIS

Progressive volvulus of small intestine

ANATOMICAL DIAGNOSIS

Carcinoids, multiple, of the ileum, with regional metastasis

PATHOLOGICAL DISCUSSION

DR MALLORY The resected loop of ileum shows a number of disk-like plaques in the mucosa or submucosa varying from 3 to 6 mm in diameter. Some of them had extended through the muscularis to the serosa, but none actually reached the surface of the latter. There was no mucosal ulceration over any of them, and none of them were large enough to have produced any obstruction. The main tumor mass was, as Dr Thompson said, in the mesentery and represented a metastasis in a mesenteric node. It measured about 4 cm. in diameter. These findings are very characteristic and could hardly result from anything except so-called "carcinoid" tumor of the bowel.

Although carcinoids are rather uncommon tumors we have seen three within the last two months. The story is almost always the same, that of small-bowel obstruction due not to the primary tumor, which rarely reaches a diameter of over a centimeter, but to a mesenteric metastasis which results in adhesions or volvulus. It is also common to find multiple primary tumors, whereas the metastasis is apt to be single. Even with metastasis the prognosis is excellent, since, though local metastasis is common, generalized metastasis is extremely rare. We have one case, for instance, followed for twenty years after resection of a segment of ileum. At the operation metastatic nodes were noted deep in the mesentery. At the time of death from lobar pneumonia they were still present but the tumor had not extended any further throughout that period.

DR WYMAN RICHARDSON What is a carcinoid—an endothelial tumor?

DR MALLORY The pathognomonic feature from the histological point of view is that the tumor cells are argentaffin. That means that, if you stain them with a proper ammoniacal silver nitrate solution, black granules can be demonstrated in the cytoplasm. The adrenal medulla and various other tissues give this same staining reaction. Argentaffin cells are found normally throughout the intestinal mucosa from the stomach to the rectum. Tumors arising from them are uncommon, however, except in certain locations. The tumors occur most commonly in the appendix, where they rarely give rise even to local metastases. The next

commonest site is the ileum, where they are almost always invasive and frequently spread to the regional nodes. Cases with generalized metastases have been reported, but they are extremely rare.

DR. WALTER BAUER What does the lesion look like microscopically?

DR. MALLORY If you look at it with low power you might think of a basal-cell carcinoma of the skin. You see anastomosing cords of deeply basophilic cells, but the cells are quite small, not spindle shaped, and extremely uniform in size. Once in a while minute glandular spaces are formed, but glands are unusual. To the experienced eye the picture is unmistakable without any special staining technic. The architecture is that of carcinoma but the uniform, small cells and the absence of mitotic activity or nuclear atypicality rule out carcinoma.

DR. JOHN D. STEWART In light of the type of the lesion would you advise going back for the two nodules outside the field of operation?

DR. MALLORY I should not at his age. I am quite sure he will die of something else.

A PHYSICIAN Was the primary tumor single or multiple?

DR. MALLORY I think there were several, separate primary tumors, any one of which could have given rise to metastases, but have no way of knowing. They all look quite invasive but otherwise nonmalignant.

DR. ARTHUR W. ALLEN Did any of the nodules ulcerate the mucosa or were they all in the wall of the bowel?

DR. MALLORY They were all in the submucosa. Even when they invade the mucosa they never ulcerate.

ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY

THE scientific program for the annual meeting of the Massachusetts Medical Society has in past years been split up, for the most part, into meetings of the various sections. This method of presentation has had the disadvantage of not allowing for a co-ordination of broad topics as they relate to the general practitioner. To those responsible for the arrangements it seemed wise to present a unified and continuous program rather than a divided one, and this was so voted last autumn at a meeting of the section chairmen and secretaries and the Committee of Arrangements. That this should be a desirable change was predicted by the success of the combined clinical meetings that have been held during one day of the sessions for the past three years. It has the further advantage of allow-

ing members in all specialties, some of which are not represented by sections, to take part

In planning the program according to these ideas it has been possible to schedule what appears to be a sufficient amount of material in a two-day meeting. The annual dinner will take place on the evening of the first day, Tuesday, May 21, and will be followed by the Shattuck Lecture. The meeting will be finished late in the afternoon of the second day.

Tuesday morning will be devoted to a consideration of miscellaneous topics presented from the point of view of the surgeon, pathologist, obstetrician, internist, urologist and radiologist. On Tuesday afternoon there will be a symposium on respiratory-tract infections. This will include papers on the common cold, bronchiectasis, lung abscess and tuberculosis. Dr. Francis G. Blake, of New Haven, will present the latest views on the treatment of pneumonia. Wednesday morning is to be taken up by a symposium on syphilis, and in this, the Society is fortunate in having Dr. Thomas Parran, of the United States Public Health Service, as a participant. Wednesday afternoon will be devoted to a symposium on sulfanilamide and allied compounds, various aspects of the use of such drugs will be considered, with a summarizing discussion by Dr. Perrin H. Long, of Baltimore. There is to be discussion of most of the papers, but in each case this has been assigned. Owing to the number of papers to be presented, open discussion will not be possible.

Because the round-table discussions inaugurated last year by the Worcester committee were so successful, it has been decided to continue them, with modification. They are to be under the direction of the various sections and will be held at nearby hotels and the University Club from noon to 2:00 p.m. on the first day of the meeting. Five subjects will be taken up, and an opportunity will be given for informal discussion of each, to be led by an authority in each field. Each meeting will be preceded by a luncheon, and it will be necessary for the Committee of Arrangements to have a general idea of the number planning to attend. Therefore, the cards enclosed with the preliminary programs must be promptly returned.

In addition to the scientific program and the round-table discussions there will be a large number of scientific and commercial exhibits. The moving pictures were more popular last year than previously, presumably because a timetable of topics was published in advance, a similar schedule will be followed this year.

All in all the entire program is comprehensive and well co-ordinated and should offer wider opportunity than ever before for the members to learn and to discuss present trends and developments of medical knowledge.

GERIATRICS

THROUGHOUT the life cycle, the responses of the body to environmental and intrinsic factors are constantly changing. There are, however, two periods in particular during which the reactivity of tissues and organs differs considerably from what one may call the "average" responses. These are the years of infancy and childhood and those of old age. The behavior of the human organism during its early developmental period has been studied extensively, but the nature of the involuntary processes of old age has received relatively little scientific attention. Geriatrics as compared with pediatrics has been little cultivated.

The diseases and the behavior of the body in old age cannot be looked on as simple quantitative deviations from the norm. Just as many diseases of infancy and childhood are specific or essentially different from those of adults, so also are the diseases of the aged. Old age is characterized primarily by a reduced reserve of all organs and functions and by a generalized narrowing of the homeostatic adaptations. These changes alter the symptoms, signs and prognosis of diseases in this group, and in addition there are disorders specific to the old. Surgery in the aged also requires special consideration, and remarkable advances have been made recently in this branch of medicine. Finally, the altered response of senile persons to drugs and other therapeutic agents should be recognized by physicians.

Further progress in the care of the aged depends on extensive systematic investigation in the field

of geriatrics. Canstadt (1839), Geist (1860), Charcot (1868), Schwalbe (1909) and Schlesinger (1914) have emphasized the importance of diseases of old age, and it is of interest that a modern textbook describing such diseases is now available.* Contributions such as the one that appears in this issue of the *Journal* represent much needed information.

As the result of the recent progress in public health, preventive medicine and pharmacotherapy, it is expected that the average duration of life will be further prolonged. This increase in the number of the aged places added responsibility on physicians to secure more comfort and better medical and surgical care for them. There seems little doubt that geriatrics will become an important branch of medicine!

MEDICAL EPONYM

BRIGHT'S DISEASE

Richard Bright (1789-1858) lecturer on the practice of medicine and one of the physicians to Guy's Hospital, included in his *Reports of Medical Cases Selected with a View of Illustrating the Symptoms and Cure of Diseases by a Reference to Morbid Anatomy* (London: Longman, Rees, Orme, Brown and Green, 1827) the results of his investigations of the pathologic conditions associated with albuminous urine. Their epoch making character has served to attach his name permanently to the whole group of nonsurgical diseases of the kidney. The following quotation is taken from the introductory remarks of the author:

The different diseases of the heart and of the lungs on which dropsy depends, and the various changes to which the liver is subject rendering it a cause of impediment to the circulation are still open to much investigation.

There are other appearances to which I think too little attention has hitherto been paid. They are those evidences of organic change which occasionally present themselves in the structure of the KIDNEY and which, whether they are to be considered as the cause of the dropsical effusion or as the consequence of some other disease cannot be unimportant. Where those conditions of the kidney to which I allude have occurred I have often found the dropsy connected with the secretion of albuminous urine, more or less coagulable on the application of heat. I have in general found that the liver has not in these cases betrayed any considerable marks of disease either during life or on exami-

nation after death, though occasionally incipient disorganization of a peculiar kind has been traced in that organ. On the other hand, I have found that where the dropsy has depended on organic change in the liver, even in the most aggravated state of such change no diseased structure has generally been discovered in the kidneys, and the urine has not coagulated by heat. I have never yet examined the body of a patient dying with dropsy attended with coagulable urine in whom some obvious derangement was not discovered in the kidneys

OBITUARY

HERMAN FRANK VICKERY

1856-1940

The death of Dr Herman F Vickery must not pass without a tribute to the worth and importance of his life. For, although he retired many years ago, he played a prominent part in establishing the foundations upon which, in Boston, our present medical structure has developed.

He was born in Rochester, New York, in 1856. Graduating in 1878 from Harvard College and in 1882 from Harvard Medical School, he was a leader in scholarship and was highly regarded by his classmates for his earnestness and sincerity. He served with credit as a house pupil at the Massachusetts General Hospital, starting in 1882, and followed this with a year of study at the University of Leipzig and at the Vienna General Hospital. Returning to Boston in 1883 he entered on the practice of medicine, in which he continued until 1917, from 1884 onward he was identified with the work of the Massachusetts General Hospital and the clinical instruction at the Harvard Medical School.

The period of nearly four decades in which Dr Vickery served was one in which medicine underwent a process of extraordinary development. During his internship, surgeons still operated in frock coats, medical therapeutics depended principally on empirical pharmacology, and laboratory diagnosis included little more than urinalysis. At the time of his retirement, medical procedure had assumed a general pattern essentially similar to that of today. In the interval, among other advances too numerous to mention, there were introduced the clinical applications of bacteriology in tuberculosis, diphtheria, typhoid fever, syphilis and other diseases, which revolutionized diagnosis and prophylaxis and, in some, treatment. Abdominal surgery, gaining impetus from the recognition of appendicitis, accomplished the major part of its impressive development. The x-ray machine, the sphygmomanometer and the electrocardiograph

were invented, and technics developed. Clinical and experimental research added many new conceptions and led to the progressive evolution of the clinical laboratory. And it is to be remembered that, coincidentally with these advances, there were constantly appearing, in even greater volume, claims of discoveries which were not substantiated, so that it was only by a laborious process of proving the true and eliminating the false that sound progress was attained.

Throughout these decades, Dr Vickery served the hospital faithfully and efficiently, advancing through the years in the responsibility of his position and in the esteem of his colleagues. While he was somewhat overshadowed by his two outstanding seniors, Dr Reginald H Fitz and Dr Frederick C Shattuck, his careful and painstaking approach together with his knowledge of medicine and his insight into human nature caused him to be recognized as an exceptional clinician. Although the requirements of his large private practice precluded original research, he exercised a most wholesome influence through a highly developed critical ability that enabled him to evaluate the publications of others with unusual accuracy, thus escaping the pitfalls of current fallacies while confirming and utilizing real advances. Through his long period of service to the hospital he demonstrated by example the value of clear vision and sound conservative judgment, and it was by these qualities more than by precept that he earned the enduring gratitude and appreciation of the long succession of interns who served under him. He also set a noteworthy standard by the meticulous performance of all his duties. If, as is often said, the Massachusetts General Hospital is outstanding for the conscientious thoroughness of its routine work, there is probably no one who did more to justify this reputation than did Dr Vickery.

He was honored by election to the presidencies of the Boylston Medical Society, the Boston Society for Medical Improvement and the Suffolk District Medical Society, and to membership in the Association of American Physicians. He was associate editor of Sajous's *Annual and Cyclopedia of the Medical Sciences*, and to this he contributed articles, notably on rheumatic fever, chorea and rheumatic heart disease, containing original observations still credited with influencing our present conceptions. He published a translation of Strümpell's *Textbook of Medicine*. He was the first in this country to report cases of psittacosis. But, more than for his publications, he is to be remembered for the influence of his life of service in sustaining and consolidating medical progress.

PUERPERAL SEPSIS FOLLOWING
NORMAL DELIVERY

Mrs. M., a thirty-eight year-old para IV, about thirty six weeks pregnant, entered the hospital on the afternoon of March 14, 1940, the membranes had ruptured twenty four hours previously, and she was having indefinite contractions.

The family history was negative. The patient's past history included the usual children's diseases and diphtheria. The tonsils had been removed and in 1929 a suspension and appendectomy had been performed. The three previous pregnancies and deliveries were uneventful, there was no history of miscarriage. Catamenia began at twelve and were regular, with a twenty-eight-day cycle. The last normal period was July 10, 1939, making the expected date of confinement April 17. The pregnancy had been normal and uneventful until the day of entry to the hospital.

Rectal examination at 7 p.m. showed the cervix to be three-fingers dilated and very soft. A normal delivery was effected at 7.30 p.m. The baby was a boy and seemed in good condition, he was not weighed. The placenta and membranes were delivered intact.

The following morning, twelve hours after delivery, the temperature was 99.6°F, and the pulse 110. Four hours later the temperature was normal, but in the afternoon, following a slight chill, the temperature rose to 103.2°F, with a pulse of 116. The temperature gradually fell during the night until it was again normal. At 9 a.m. the next day, March 16, following a slight chilly sensation, the temperature went to 102.0°F, and later in the day to 102.6. Physical examination showed a somewhat reddened throat and a slightly distended abdomen, the lochia was not remarkable. A consultation was immediately held with a surgical bacteriologist. Cultures were taken from the lochia, throat and blood stream, and all eventually showed hemolytic streptococci. Sulfapyridine was started even before the results of the cultures and smears had been reported. It was given in doses of 15 gr every hour for four doses and subsequently 15 gr every four hours. After the cultures had been reported, the drug was changed to sulfanilamide.

The dosage was 20 gr every four hours for twenty four hours, then 15 gr every four hours, and subsequently 10 gr every four hours, until it was finally omitted on March 22.

The temperature came down to normal on March 18 and so remained throughout the subsequent convalescence. She was discharged in good condition on March 31, the seventeenth day after delivery.

The following white counts are of interest: March 16, 18,900; March 20, 21,000; March 21, 27,400; March 22, 29,900; March 23, 29,900; March 25, 26,400; March 26, 17,800; March 27, 14,900; March 28, 16,700; March 29, 12,600; March 30, 10,000. The sustained increased white count following the drop of the temperature to normal was probably due to the sulfanilamide.

Comment. This case illustrates the proper handling of certain cases of puerperal sepsis. The temperature of 99.6°F twelve hours after delivery with a rise to 102.6 eight hours later, suggests that the infection was present at the time of delivery. The administration of sulfapyridine before the cultures were reported and the shift to sulfanilamide afterward show the use of intelligent chemotherapy based on knowledge of the true etiologic factor. The uterus was left entirely alone.

MEDICAL POSTGRADUATE
EXTENSION COURSES

The following sessions given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau have been arranged for the week beginning April 21:

BRISTOL SOUTH (Fall River Section)

Tuesday April 23 at 4.30 p.m. at the Union Hospital, Fall River. Syphilis in Pregnancy and the Offspring. Instructor Francis M. Thurmon. Howard P. Sawyer, *Chairman*.

HAMPSHIRE

Thursday April 25 at 4.00 p.m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8.15 p.m. in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Complications in Obstetrics, illustrated by Case Histories. Instructor Roy J. Heffernan. George L. Schadt, *Chairman*.

HAMPSHIRE

Thursday April 25 at 4.15 p.m., in the Nurses' Home of the Cooley Dickinson Hospital, Northampton. Syphilis in Pregnancy and the Offspring. Instructor Francis M. Thurmon. Warren P. Cordes, *Chairman*.

MIDDLESEX SOUTH

Tuesday April 23 at 4.30 p.m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Gonorrhea in the Female. Instructor Sylvester B. Kelley. Dudley Merrill, *Chairman*.

*A series of selected case histories by members of the section will be published, with comments and questions by subscribers are solicited and will be discussed by members of the section.

NORFOLK SOUTH

Monday, April 22, at 8 30 p.m., at the Quincy City Hospital, Quincy Cardiovascular Disease Eleven important questions about heart disease and their answers Instructor Burton E. Hamilton. David L. Belding, *Chairman*

PLYMOUTH

Tuesday, April 23, at 4 00 p.m., in the Nurses' Home of the Brockton Hospital, Brockton Head and Spine Injuries Instructor Donald Munro Walter H. Pulsifer, *Chairman*

DEATHS

LORD—SIDNEY A. LORD, M.D., of Boston died March 30. He was in his seventy-second year.

Dr. Lord received his degree from the Harvard Medical School in 1894 and specialized in neurology. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

VAN GAASBEEK—GEORGE H. VAN GAASBEEK, M.D., of Springfield, died January 22. He was in his seventy-seventh year.

Dr. Van Gaasbeek received his degree from the Albany Medical College in 1893. He was a member of the Massachusetts Medical Society and the American Medical Association.

MISCELLANY

WHAT THE DOCTOR SHOULD KNOW

April is the month in which tuberculosis associations proclaim the importance of the early diagnosis of tuberculosis. Through various channels of publicity the public is urged to take heed of the early symptoms. They are told also about the advantage of the tuberculin test and the x-ray as means of discovering tuberculosis even before symptoms appear. Physicians play their part by meeting the demand for more prompt and precise diagnosis. Dr. Henry C. Sweeney of the Research Laboratories of the City of Chicago Municipal Tuberculous Sanatorium, who has contributed the following sees clinical tuberculosis through the eyes of the pathologist familiar with end results. An understanding of what lies beneath the often obscure signs of approaching tuberculosis should be valuable to the practitioner whose field of battle is mostly in the sick room.

in the April 11 issue of the *Journal*. The revised program is as follows.

Presentation of cases.

Some Problems in the Proper Emptying of Hollow Viscera. Dr W J Merle Scott, of Rochester, New York.

JOINT MEETING OF THE SUFFOLK DISTRICT MEDICAL SOCIETY AND THE BOSTON MEDICAL LIBRARY

A joint meeting of the Suffolk District Medical Society and the Boston Medical Library will be held on Wednesday evening, April 24, at 8 15 at the Boston Medical Library, 8 Fenway, Boston.

PROGRAM

Official reports of the Society for 1938.

Election of officers.

Atom Smashing as a New Tool for Medical Research (with demonstration) Dr J J Livingood. Discussion will be opened by Drs. Shields Warren Francis T Hunter and Saul Hertz.

BOSTON DOCTORS' SYMPHONY ORCHESTRA

The first concert of the Boston Doctors' Symphony Orchestra, Alexander Thiede, conductor, will be held at 8 15 on Sunday evening, May 5 at Jordan Hall. Tickets are priced at one dollar and the proceeds will be given to a medical charity. The ticket committee is composed of Dr Welman B. Christe, chairman, 15 Bay State Road, Boston; Dr Julius Loman, 1284 Beacon Street, Brookline, and Dr Robert G Vance, 262 Beacon Street, Boston.

HENRY JACKSON LECTURE

The Henry Jackson Lecture for 1940 offered by the New England Heart Association will be given by Dr Harrison S. Marland, chief medical examiner of Essex County, New Jersey and professor of forensic medicine, New York University College of Medicine. His subject will be "Sudden Deaths with Reference to Their Prevention." The lecture will be held at the Boston Medical Library on Friday, April 26, at 8 15 p.m.

Interested physicians and medical students are invited to attend.

MASSACHUSETTS DEPARTMENT OF CIVIL SERVICE AND REGISTRATION

PUBLIC WELFARE PHYSICIAN (MALE), DEPARTMENT OF PUBLIC WELFARE

Director of State Civil Service, Ulysses J. Lupien has announced that a competitive examination is to be held on May 11 in order to find eligibles for appointment to the position of Public Welfare Physician, Department of Public Welfare. The entrance salary is \$3780 a year; the maximum is \$4500 a year.

The entrance requirements are as follows: applicants must be registered physicians under the State Board of Registration in Medicine, and must have at least five years' experience in the practice of medicine, at least one year of which shall have been spent as an intern in a hospital approved for internship by the American Medical Association.

The substitution is as follows: satisfactory full-time experience in a medical administrative capacity in a hospital, public-health organization, department of public health or department of public welfare within the past five years may be substituted year for year for the years of experi-

ence required in the practice of medicine, except for the year of internship. The substitution of education is education may be substituted for experience, year for year of graduate study in a school of public health.

The subjects and weights of the examination are as follows: training and experience, 2, practical questions, 3 total, 5. Applicants must obtain a grade of 70 per cent in each subject in order to become eligible. The last date for filing applications is Saturday April 27.

NEW ENGLAND ROENTGEN RAY SOCIETY

The next meeting of the New England Roentgen Ray Society will be held in the main amphitheater of the Children's Hospital on Friday April 26, at 8:00 p.m.

PROGRAM

Cranioleptomycin. A report of 54 cases. Dr E. C. Vogt. Genitourinary Diagnosis and Treatment in Infants and Children. Persistent pyuria, kidney embryoma and retroperitoneal neuroblastoma. Drs. G. M. Wyatt and W. E. Ladd.

Tumors in Early Life. Dr. Sidney Farber.

Dinner at the Harvard Club will be served at 6:30 p.m.

SOCIETY MEETINGS AND CONFERENCES

CALNDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY, APRIL 21

TUESDAY APRIL 23

9-10 a.m. Ovarian Tumors. Dr J. T. Smith. Joseph H. Pratt Diagnostic Hospital.

12:30 p.m. An Experiment in the Delivery of Medical Care. Dr. Chesley Frothingham. Community Nursing Council of Boston. Young Women's Christian Association, 140 Clarendon Street, Boston.

8:15 p.m. Harvard Medical Society. Amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance).

WEDNESDAY APRIL 24

9-10 a.m. Hospital case presentation. Dr S. J. Thannhauser. Joseph H. Pratt Diagnostic Hospital.

2-4 p.m. Hematuria. Drs. W. C. Quinby and E. A. Brand. Peter Bent Brigham Hospital.

8 p.m. Massachusetts Dental Society. Georgian Room, Hotel Statler.

8:15 p.m. Joint meeting of the Suffolk District Medical Society and the Boston Medical Library. 8 Fenway, Boston.

THURSDAY APRIL 25

9-10 a.m. Off the Main Road in Diabetes. Dr J. J. Schlem. Joseph H. Pratt Diagnostic Hospital.

FRIDAY APRIL 26

9-10 a.m. Small-Bowel Obstruction. Dr L. S. McIntirick. Joseph H. Pratt Diagnostic Hospital.

8 p.m. The Clinical Interpretation of Bacteremia. Dr. Chester S. Keeler. Sir William Osler Honorary Society of the Tufts College Medical School. Beth Israel Hospital. 1000 Comm.

8 p.m. New England Roentgen Ray Society. Children's Hospital main amphitheater.

8:15 p.m. Sudden Deaths with Reference to Their Prevention. Dr. Harrison S. Marland. Henry Jackson Lecture. Boston Medical Library. 8 Fenway.

SATURDAY APRIL 27

9-10 a.m. Hospital case presentation. Dr Thannhauser. Joseph H. Pratt Diagnostic Hospital.

BOOK REVIEWS

The Rockefeller Foundation Annual report, 1938 515 pp New York The Rockefeller Foundation, 1939

This annual report of the Rockefeller Foundation covers, as usual, the work of the International Health Division, reports of the divisions on medical sciences, natural sciences, social sciences and the humanities and the work in China. In addition, there are the reports of the secretary, the president and the treasurer. There is an excellent index, and a number of illustrations. Such a volume cannot be easily reviewed for it covers so wide a field.

To those who are interested in what the Rockefeller Foundation is accomplishing and how its large grants of money are being allocated each year, this book is widely recommended. It is interesting to note that the appropriation for medical sciences to the China Medical Board was nearly four million dollars. One of the major activities of the Foundation has been in relation to psychiatry, neurology and related subjects. In 1938, it helped to develop departments of neurology and psychiatry in five medical schools, with the expenditure of over two million dollars. In looking to the future, the president points out that fields of medical research which might be expanded include chemotherapy, dermatology, pharmacology, legal medicine, industrial medicine, dentistry, public health and the diseases of advancing years.

Handbook of Orthopaedic Surgery Alfred R. Shands, Jr. In collaboration with Richard B Raney. Second edition. 567 pp St. Louis C V Mosby Co, 1940 \$4.25

The first edition of this book has found a definite place in the teaching of orthopedic surgery to medical students and is valuable to those in general practice because the essentials are briefly stated, and the subjects well covered. The new edition is smaller than the first, chiefly because the paper is thinner, rather than because of changes in material. The book is divided into twenty-four chapters, corresponding to the number of hours ordinarily devoted to lectures on the subject in the average medical school.

The illustrations are made up of line drawings, there being no direct reproductions of x-ray films or pathologic specimens. This makes for simplicity without affecting the value of the book for teaching purposes. A valuable part of both the first and second editions, especially for medical students, is the current bibliography, rather selective, corresponding to each chapter and confined to the English language. This gives the student a chance for further reading without making too many demands in the searching for collateral titles.

NUMBER 17

THE RATIONALE AND TECHNIC OF SYMPATHECTOMY FOR THE RELIEF OF VASCULAR SPASM OF THE EXTREMITIES*

REGINALD H. SMITHWICK, M.D.†

BOSTON

TIME and experience have shown that any operation having for its purpose the interruption of sympathetic impulses to the blood vessels of the extremities must fulfill three qualifications. First, it must be anatomically complete. Second, it must be physiologically sound. Third, it must be performed in a manner that guards against the regeneration of nerve fibers. The object of this paper is twofold. First, these three matters will be briefly discussed. They have been considered in greater detail elsewhere.¹ Second, the operative technique that I have found best to satisfy these requirements in the case of both the upper and the lower extremity will be described.

To say that an operation must be complete would appear to be an unnecessary statement. If the anatomical arrangement of sympathetic motor pathways to the extremities had been better understood, this would not have been such a difficult problem with which to cope. Obviously, one should know not only the exact segments of the cord that supply vasomotor and sudomotor fibers to the extremities, but also their exact course through the sympathetic trunk after emergence from the spinal cord by way of the white rami communicantes. While this knowledge is not complete, enough is known to state which portion of the outlying sympathetic trunk should be interrupted in order to produce the desired effect. This information has been acquired only by trial and error, and by careful observation of the clinical effect of various operative procedures. The anatomical details will be given in the description of operative technic.

For many years, physiologists have known that a sympathetic motor nerve is composed of two parts. The first portion extends from the gray matter of the cord to an outlying sympathetic gan-

glion. The latter point is reached by way of the anterior roots and white communicating rami. The second portion extends from the ganglion, where the synapse between the two lies, to the blood vessel wall in which the fiber terminates. This point is reached by way of gray communicating rami and the peripheral nerves.

Immediately after a blood vessel is completely disconnected from central vasoconstrictor impulses, maximal relaxation of the arterial smooth muscle follows. This results in maximal blood flow to the part. By the end of three weeks, however, the arteries regain a certain amount of their tone, and a compensatory mechanism for increasing this tone in response to pain, cold and emotion appears. Thus circulating hormones, adrenaline in particular, carried in the blood stream to the vessel wall, are able to produce vasoconstriction.^{2,3} It has been demonstrated beyond doubt that if the second or postganglionic portion of the pathway has been divided, this compensatory humoral action is approximately three times as great as that resulting from division of the first or preganglionic portion.⁴ Hence it becomes apparent that a surgical procedure should, so far as possible, interrupt only preganglionic fibers in order to produce maximal vascular relaxation and maximal blood flow to the part, and to minimize residual vasoconstriction due to this humoral mechanism. An operation therefore should be complete and, furthermore, preganglionic in type.

The ability of sympathetic motor nerves to regenerate makes it imperative to take steps to guard against this action in order to obtain lasting results. Time has shown that a wide separation of the divided ends of the resected nerves is the best assurance against regeneration. The lumbar portion of the sympathetic trunk with its long communicating rami enables one to perform a wide resection of these structures, resulting in adequate separation of the divided parts (several centimeters). At the same time, the location of the

*From the surgical services and the Peripheral Vascular Clinic, Massachusetts General Hospital, Boston. Read by title at the annual meeting of the New England Surgical Society, Salem, Massachusetts, September 29-30, 1939.

†Instructor in surgery, Harvard Medical School; assistant visiting surgeon, Massachusetts General Hospital, Boston.

synapses is such that a preganglionic type of operation can be done

In the case of the upper extremity, however, the problem is much more difficult. Here, the length of the ramus is short. Wide resection of the trunk and ganglia concerned results in a postganglionic type of operation, and even so has been found not to prevent regeneration. It has therefore been necessary to resort to section of the anterior roots within the arachnoid, and to separate the divided ends of the trunk widely. The details of this maneuver will be considered under operative technique.

THE UPPER EXTREMITY

General Considerations

The operation to be described is the result of years of trial and error. Many different procedures have been utilized. The difficulties encountered have been previously reported by me⁶ as well as by others^{6, 7}. The present operation has been used in principle for nearly five years. Several modifications have been made. The technique to be described has been in use for nearly two years, and is reported in detail in its present form because I believe that the results are satisfactory, and that no fundamental changes will be necessary.

Anatomically, the sympathetic outflow from the second and third dorsal segments is interrupted by dividing the anterior roots of the second and third intercostal nerves within the arachnoid. The sympathetic trunk is sectioned below its third ganglion. The upper sectioned end is sutured into the wound, the distal end being ligated. This results in a complete sympathetic denervation of the upper extremity, with the exception of any fibers that may be contained in the first dorsal nerve. There is no feasible way to section the outflow from this segment in man in a manner that will prevent regeneration and not cut postganglionic pathways or somatic motor fibers running to the arm. Experience has shown that the sympathetic supply to the arm from this source is not sufficient to be of clinical importance. This operation guards against regeneration because the anterior roots are divided within the arachnoid. The proximal cut ends are therefore within a watertight compartment, and after the meninges heal, regeneration should be impossible. Also, not only are the divided ends of the sympathetic trunk widely separated, but also the upper end is outside the thorax, the lower within. The operation meets the stated requirements of being adequate and preganglionic in type and of guarding against regeneration.

Operative Technique

Under intratracheal anesthesia, a vertical paravertebral incision is made, 7 cm. long and about

5 cm. lateral to the midline. It is centered opposite the space between the second and third dorsal spinous processes. The trapezius fibers are divided transversely for 4 cm. in the center of the wound. The underlying rhomboid muscle is split in the direction of its fibers. A finger can then be passed upward and downward beneath this muscle, and the third rib accurately identified. The inner 4 cm. of this rib is removed through a vertical split in the longissimus capitis muscle. The tip of the transverse process is resected and the underlying rib fragment beveled. The pleura is gently separated to the midline of the vertebral column, to above the second rib and to a point below the fourth rib (Fig. 1).

The third intercostal nerve is next divided at the lateral border of the incision. It is held in a hemostat and lowered into the wound. Dissection is

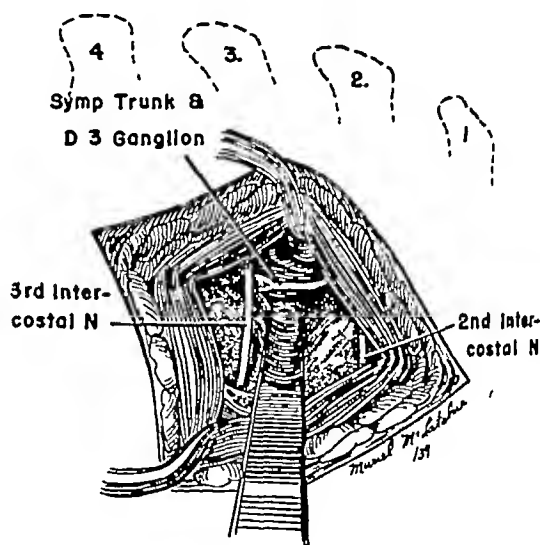

FIGURE 1

carried medially along the nerve, dividing first the gray ramus, second the dorsal branch and finally the white ramus. The posterior root ganglion is then clearly seen. A dental spatula can be slipped between the anterior and posterior roots. The latter is divided just proximal to its ganglion, exposing the anterior root as the sole remaining structure. The meninges are gently pushed inwardly along this root until the white, glistening intraspinal portion is brought into view. This is divided, the proximal end retracting within the arachnoid. A spinal-fluid leak of no consequence results from this maneuver. A sketch of a typical specimen of an intercostal nerve removed is shown in Figure 2.

The same procedure is carried out in the case of the second intercostal nerve (Fig. 3). The final step is to divide the sympathetic trunk below the third ganglion (Fig. 4). The distal end

is ligated within the thorax. The proximal end is brought out and sutured into the muscles of the incision (Fig 5). More recently, the decentralized second and third dorsal ganglia have been covered with a fine silk cylinder to guard further against regeneration. Occasionally an opening in the pleura is inadvertently made. It is best not to try to close it, no difficulty will be encountered if the lung is fully expanded and the extrapleural

removal of the first, second and third lumbar ganglia results in complete sympathetic denervation of the thigh and leg. Removal of the second and third ganglia results in a nearly complete denervation of the leg from the knee distally, but the effect on the thigh is not necessarily complete. The

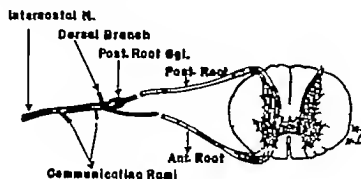

FIGURE 2.

air space obliterated by positive intratracheal pressure before closing the wound tightly. Drainage is never instituted. Silk suture technic is used. The upper extremities are always denervated separately, about a week apart. There have been no deaths and no serious complications. Between January 24, 1935, and November 1, 1939, one hundred and forty-two upper extremities (82 patients) were denervated by this type of operation.

THE LOWER EXTREMITY

General Considerations

Anatomically, the lower extremity is best denervated by excision of a portion of the lumbar

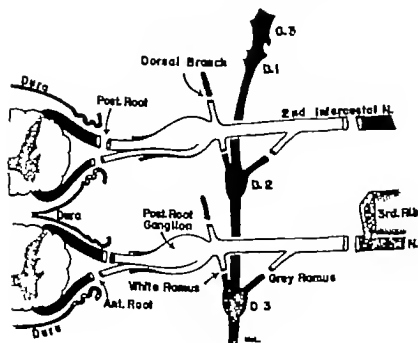

FIGURE 3.

trunk. This contains four ganglia as a rule, but anatomical variations are common. Study of the postoperative effects of interruption of various portions of the lumbar trunk has shown that re-

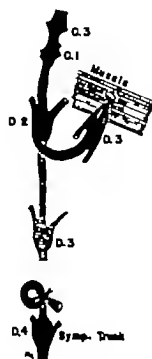

FIGURE 4

former operation is preferable from the point of view of completeness, but has the disadvantage of interfering with ejaculation in men, owing to excision of the first lumbar ganglion. Both pro-

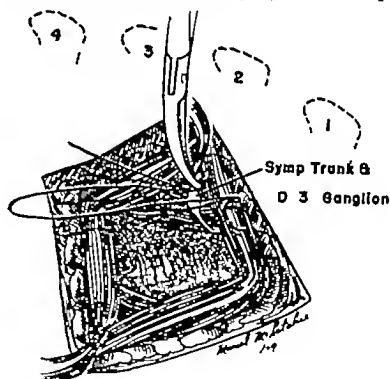

FIGURE 5

cedures interrupt largely preganglionic fibers running to the leg below the knee, and both seem extensive enough to prevent any regeneration of consequence. Removal of the fourth ganglion adds nothing to the completeness of the operation, and has the disadvantage of interrupting postganglionic fibers running to the lower leg. Most of these arise in the fourth lumbar and upper two or three sacral ganglia.

Sympathetic denervation of the lower extremity as described above is adequate, is largely preganglionic in type and ensures against regeneration of interrupted nerve pathways. As a routine procedure, excision of a portion of the lumbar trunk, including its first, second and third ganglia, and resection of the corresponding communicating rami are practiced in women. In men, the first lumbar ganglion and its communicating rami are not disturbed unless it is thought that the underlying vascular problem justifies their removal. The clinical results so far as relief of vascular spasm is concerned are uniformly satisfactory. Between May 26, 1936, and November 1, 1939, one hundred and three lower extremities (62 patients) were denervated by this technic. There was 1 death due to a pulmonary embolus.

It can be seen that the main purpose is to expose the upper portion of the lumbar sympathetic trunk. Experience has shown that this region is best approached by the extraperitoneal route. If both sides are to be done, the operations are spaced one week apart. This approach is far superior to the transperitoneal operation, which we used extensively up to three years ago. Such a laparotomy is a much more difficult task, and subjects the patient to unnecessary risk and discomfort. Its field of application must necessarily be narrowed to good-risk patients and to those who are certain to derive great benefit from it. Moreover, it is almost impossible to remove the first lumbar ganglion by this route, and often the second ganglion is reached with difficulty if at all. Frequently the third and fourth ganglia are removed, an undesirable step for reasons previously stated. The only advantage of the abdominal approach is that both lower extremities can be denervated at the same time. The many advantages of the extraperitoneal route far outweigh this. A number of excellent extraperitoneal procedures have been described.⁸⁻¹⁰ The following one is that which I have found most useful.

Operative Technic

Either general or spinal anesthesia is used. The latter gives excellent muscular relaxation, and perhaps has an advantage in heavily built individuals. Silk-suture technic is preferred. Drainage is never used.

The patient is placed on his side, with a kidney bar in place just above the level of the iliac crest. The operative field is uppermost. Both knees are drawn upward so that the thighs are approximately at a right angle with the abdomen. This relaxes the *iliopsoas* muscle group. A medium-sized pillow is placed beneath the undermost

thigh, a second pillow is placed between the two thighs and the undermost shoulder is drawn forward. All these steps tend to tilt the patient backward toward the operator. This position is maintained by a strap running diagonally over the legs just below the knees, and by a padded support placed against the sacrum and the back in the scapular region. The kidney bar is then elevated, widening the space between the twelfth rib and the iliac crest and stretching the external oblique muscle. This effect can be intensified by lowering the head and foot of the table a little. The final move is to tilt the table so that the plane of the patient's back is 30 to 45° from the vertical position toward the operator. The latter stands facing the patient's back.

An incision is made, starting in the angle formed by the twelfth rib and the sacrospinalis muscle group (Fig 6). It runs anteriorly 1 cm below

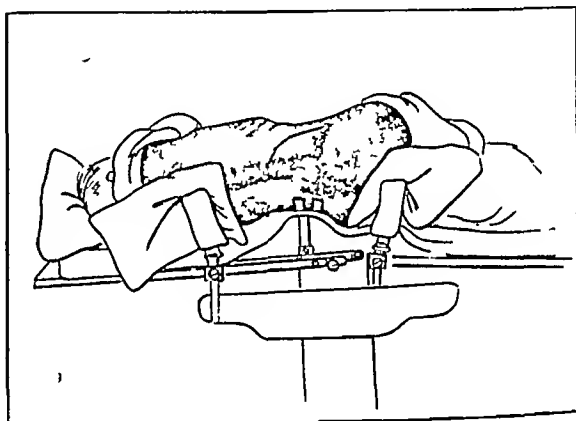

FIGURE 6

the rib to its tip, then curves anteriorly and downward over the posterior border of the external oblique muscle to the iliac crest. It meets the latter at a point about 7 cm posterior to the anterosuperior iliac spine. In the posterior portion of the wound, a few fibers of the latissimus dorsi are cut across. The posterior border of the external oblique muscle as it runs from the tip of the twelfth rib to the iliac crest is dissected out and retracted forward. This exposes the internal oblique muscle, whose fibers are divided for about 2 cm by an incision parallel to the twelfth rib. The lumbodorsal fascia is next incised for 7 cm in the line of its fibers 1 cm below and parallel to the twelfth rib. The twelfth nerve lies just above and the first lumbar nerve just below the incision. The first lumbar nerve is plainly seen running downward and forward along the lateral border of the quadratus lumborum muscle (Fig 7).

A finger is then passed inward, upward and

medially just below the twelfth rib, over the quadratus lumborum and iliopsoas muscles and posterior to the lower pole of the kidney and peritoneum. It meets the vertebral column in the region of the first lumbar vertebra. The sympathetic trunk is readily palpated on the anterolateral aspect of the spinal column. The finger is gently passed from above downward, separating the peritoneum from the iliopsoas and quadratus lumborum muscles until the trunk has been exposed to be low its third ganglion.

A loog, moist strip of gauze is gently inserted against the peritoneum, and the latter, including the ureter, and also the vena cava or aorta, can

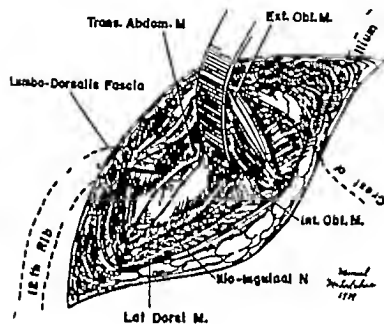

FIGURE 7

then be gently retracted upward and anteriorly with a long, curved retractor such as the Dever type (Fig 8). Because of the position of the patient, one can look directly at the sympathetic trunk over the iliopsoas muscle group. It is not necessary to use any posterior retraction except for lighting purposes. The sympathetic trunk is plainly seen, with its second and third ganglia and sets of communicating rami. The first lumbar ganglion and its rami as a rule cannot be perceived until the avascular fascia of the lumbocostal arch has been divided in an upward direction for about 2 cm. On the right side, lumbar veins running into the vena cava may cross over the trunk. This is particularly true of a large, constant branch just below the communicating rami of the third lumbar ganglion. The desired

portion of the sympathetic trunk and communicating rami can then be readily removed. This step is facilitated by special instruments, among

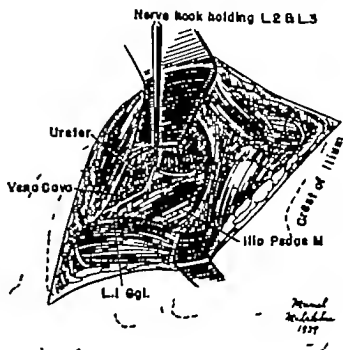

FIGURE 8.

which long Crile hooks and Hartman forceps are particularly useful.

SUMMARY

The rationale of sympathetic denervation of the extremities is discussed.

The surgical technic that I have found to give the best clinical results in the case of both the upper and the lower extremities is described in detail.

COMPRESSIONS OF THE VERTEBRAL BODIES DURING CONVULSIVE THERAPY*

Preliminary Note Regarding Their Prevention

EMERICK FRIEDMAN, M.D.,† A LEO BRETT, M.D.,‡ AND EDWARD C VOGT, M.D.§

WALTHAM, MASSACHUSETTS

IN A recent publication by one of us (E F¹), in which a comprehensive search for complications of convulsive therapy of the psychoses was attempted, hardly pertinent data could be gleaned from the reports of seventy-five clinics with reference to vertebral injuries. The surprising scarcity of subjective complaints referable to the back, even in patients who demonstrate a tendency toward hypochondriasis during convulsive therapy, —seeking any excuse to be released from treatment,—is probably responsible in great part for the belated recognition of this mechanical complication. Another possible cause is the often severe divergence in interest between psychiatric and orthopedic workers. It is believed in retrospect that had an experienced orthopedic surgeon viewed a number of therapeutic convulsions during the incipient days of convulsant therapy, most of the now better-known mechanical complications might have been prevented, such as was done in the preventing of fractures or dislocations at the shoulder and hip joints by methods suggested in the previous paper.

In view of the relatively recent reports by Polatin et al.,² Stalker,³ Wespi,⁴ and Bennett and Fitzpatrick⁵ regarding dorsal compressions, we have referred to their data concerning accidental compression injuries of the vertebrae. From these sources the uniform conclusion is evident that vertebral compressions occur almost exclusively when the vertebral column is in the flexed position. The similarity between this position in accidental compression and that of the spine during the induced convulsive process is explained in greater detail below.

ANATOMICAL AND ORTHOPEDIC CONSIDERATIONS⁶

The underlying structural peculiarities of the dorsal spine that tend to facilitate compression injuries of this region during induced grand-mal reactions may be briefly described. The dorsal curvature is the first of the spinal curves to develop or to be noticed phylogenetically, it is the first to become fixed in normal skeletal development. The dorsal vertebrae, in contrast to those of the cervical and lumbar regions, form normally

an anterior concavity which in the assumption of the upright position brings about a thinning of the anterior portion of the intervertebral fibrocartilage. The disks as well are generally thinner in this region. In the thoracic spine practically all intrinsic movements are limited in order to facilitate respiratory movements via the costophrenic mechanism. The angulation of the superior articular surfaces of the dorsal vertebrae and the contiguity of the inferior articular surfaces and the laminae, together with the approximation of the dorsal spinous processes with each other, inhibit to a great extent respectively flexion and extension movements of the dorsal spine. This architecture and the distribution of the muscles of the trunk, with special favoring of the cervical and lumbar regions, combine to make for a unitary function of the dorsal spine in ordinary locomotion as well as in cases of trauma by a force acting vertically downward and thus directed on the lumbodorsal junction. On the other hand, if the direction of the force becomes reversed the tendency toward involvement of the cervical region, that is the impingement of the dorsal vertebrae as a unit, is evident. Another important feature in spinal injuries is the placement of the anterior and posterior common ligaments, which are essential for holding the vertebral bodies together. The posterior group is much more extensive and is strengthened by the adjacent interspinous and supraspinous groups, as well as by the intertransverse and interlaminar ligaments.

So long as there is a hyperflexion of the vertebral column in a given region, the requisite force imposed on it need not be great in order to cause a compression fracture of the spongy vertebral body. The force required may be even less than that which obtains in normally active people. Various undetermined factors of relative decalcification in the vertebral bodies of patients inactive for years may also play a part—the so-called bone atrophy of disuse. The immediate force must simultaneously compress the vertebral region along its longitudinal axis and flex it. The movable vertebral portion becomes fixed after sudden movement, and the momentum of the vertebral portion above this region crushes the intermediate vertebral bodies. As already mentioned, the compressions occurring in industrial orthopedic practice are found

§Consulting roentgenologist, Metropolitan State Hospital.

chiefly at the junction of the dorsal (relatively rigid) vertebrae with the lumbar or cervical (relatively flexible or resilient) regions. But this condition obtains with the spinal column perpendicular, which is not the case during the induced convulsive procedure wherein force is exerted with the column horizontally disposed. With this in mind, we come to the consideration of the mechanical factors attending the grand mal reaction per se.

The actual pattern of the Metrazol, or camphor induced, seizure has been described elsewhere.¹ The phases of this reaction in which vertebral compressions are likely to occur are the tonic

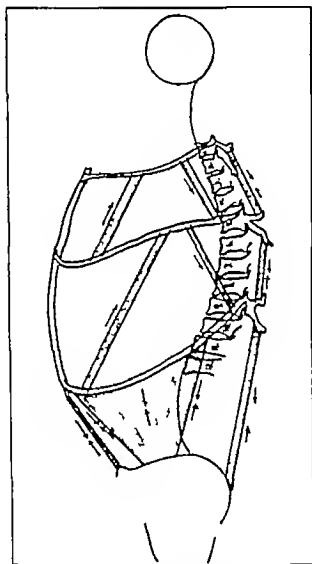

FIGURE 1

Schematization demonstrating relative extension and flexion muscular forces on the thoracic spine. The excessive leverage of the spinoflexors using the ribs as levers is quite apparent.

and the clonic. In the former the force directed on the vertebrae acts almost continuously, somewhat similar to that observed in tetanus and similar conditions*, in the latter the contractures occur in a rhythmically interrupted fashion. The tonic phase imposes a grinding type of action, the clonic phase a hammering type. In either case, an undetermined number of patients will undergo a predominantly opisthotonic phase, while others will demonstrate orthotonos, even em prothotonos. In the last two forms, particularly, the normal or accentuated dorsal curvature be-

comes the locus of converging forces. As already stated, the trunk musculature is concentrated either adjacently inferior or superior to the dorsal region, the pelvic and lower limb and the craniocervical sections jerk in opposing directions, the area of stress being the arch of the relatively rigid dorsal spine. It would appear that this phenomenon, together with the leverage of the anterior thoracic and abdominal muscles exerted through the ribs as spinoflexors during the grand mal reaction, is directly responsible for midthoracic vertebral compressions. The leverage of the anterior group of muscles appears to be proportionately many times greater than that of the posterior group, which is close to the spine itself (Fig. 1).

STATISTICS

A series of 69 patients have been treated to date by an extensive and as yet incomplete program of convulsive irritative therapy. Four patients had already been discharged on visit at the time of this study and were not available for x-ray examinations. Roentgenological examinations were completed on the remaining 65 patients, lateral, dorsal and lumbar plates being taken of each. Thirteen control patients were similarly studied. The technical details of management of this routine has been described elsewhere.¹ Here, however, we may state that the original measures to prevent mechanical complications consisted only of the application of sheet bands about the lower deltoid and mid-thigh regions so as to allow flexion extension of the upper and lower extremities but to prevent abduction of the shoulder and hip joints. Additional preventive measures were undertaken later, after it was learned that vertebral compressions might occur during the induced convulsions. This knowledge was obtained only after the courses of treatment had advanced to the degrees noted in Table 1.

No complaints referable to the back were offered, with 1 exception, this patient had negative

x ray findings. Physical examinations of the back and neurological examinations were negative. There were 11 cases of vertebral injuries that con-

formed in a general way to the diagnoses of compression fractures of the vertebral bodies. The diagnoses were based entirely on x-ray findings. These findings are listed in Table 1, together with the number of grand-mal reactions induced up to the taking of x-ray films.

One additional case of vertebral compression might be mentioned at this point. The patient, during a determined effort at escape from the hospital, jumped or fell from a second-story window. He sustained fractures of the left os calcis and left elbow. A slight compression of the eighth dorsal vertebral body was also found. From the

TABLE 2 *Observations in Control Cases*

| CASE | INTERPRETATION |
|------|--|
| P C | Apparent bulging of the nucleus pulposus between four lumbar vertebrae (2 3 4 5) probably old |
| D B | Narrowing of the disk between two lumbar vertebrae (1 2) probably old |
| C W | Bodies of six dorsal vertebrae (5 6 7 8 9 10) slightly narrowed (the uniformity of this narrowing was indicative of a postural factor) fairly marked dorsal kyphosis |
| D M | Slight narrowing of the body of one dorsal vertebra (12) not of recent origin probably the result of an injury in early life. |

nature of the other injuries the latter finding could reasonably be attributed to the same accident.

It is of interest that only the thoracic vertebrae were involved, the tendency toward involvement of the centrally located bodies should also be noted. This may be contrasted with the involvement after accidental trauma wherein compressions rarely occur above the lowermost dorsal region. In every case the injury occurred in a patient who for a number of years before treatment had been classed as sedentary and hypokinetic. The single exception occurred in Case A C, that of one who had been active as a laborer and had participated in various entertainments, taking the part of an acrobat. We cannot now prove whether or not this activity was a factor in the presenting injury. There was no correlation between the number or apparent severity of reactions and the occurrence of compressions. For the most part these injuries were not complete fractures of the whole vertebral body, but compressions of one or more of the anterior, superior and inferior portions, causing various degrees of wedging with the base of the vertebral body spared,—again in contrast to that which obtains in industrial work,—accounting, probably, for the absence of local pain in post-convulsive cases.

The possible predisposing factors seem to be as follows: an underlying postural or osteoporotic disorder, and a temporarily co-existing mechanical feature in the handling of the patient during the induction of the convulsion. Although in this paper we intend to emphasize the latter factor, the

former must not be neglected. To date, adequate laboratory or roentgenological data to prove the existence of a calcium-phosphorus metabolic disorder are not available. Yet the impression can not be dismissed that prolonged relative inactivity of the musculoskeletal system makes it more vulnerable to mechanical injuries, at least two text books⁹ refer to such an osseous condition as porosity from inactivity, and it is commonly called the atrophy of disuse.

In an attempt to gauge the possibility of pre-existing postural deformities that might contribute to an orthopedically significant extent to vertebral complications, 13 patients were chosen for x-ray examination of the spine. They were selected arbitrarily, with the mental reservation that they might later be given a course of convulsive irritative therapy. None of the patients received con-

FIGURE 2 *Case S S*

vulsive therapy. The observations in 4 of the cases are given in Table 2.

It is perhaps not strictly accurate to class these as control cases of a convulsion-treated group. However, the fact can by no means be disregarded that roentgenologically evident postural deformities do exist in a significant number of the total hospital population. Depending on the type of psychiatric ward, that is in reference to the chronicity of the illness for which the cases are segregated,

in the long standing hypokinetic cases a variety of postural deformities are commonplace, chief among these being kyphoses, round backs and stooped shoulders. We believe that the abundance of these deformities might easily be overlooked in everyday intramural psychiatric prac

FIGURE 3 Case J H

tice were it not for some unusual occurrence or set of observations such as prompted the writing of this paper. Of the group herein described existing deformities were outstanding in over 30 per cent. Vertebral compressions occurred in less than 17 per cent after treatment—we must express it thus since x-ray studies were not made before treatment was instituted.

In Figure 2 there is depicted our most severe vertebral compression as a result of treatment. This patient (Case S S) received a total of thirteen convulsions. The x-ray interpretation is compressed fractures of the fifth, sixth and seventh dorsal vertebrae, with the width of the body of the sixth reduced to about half normal. Further analysis indicates the probability of a pre-existing kyphotic postural deformity. The greatest strain was apparently directed on the central thoracic vertebrae

Our next severest injury is shown in Figure 3, which illustrates the dorsal spine of a patient (Case J H.) after undergoing twenty-two convulsions. The interpretation is definite compression of the seventh, eighth, ninth and tenth dorsal vertebrae. If we now compare the foregoing with one of the controls (Case C W), as shown in Figure 4, we have for the latter the following interpretation: the bodies of the sixth, seventh, eighth, ninth and tenth dorsal vertebrae are narrowed, the uniformity of this narrowing is, however, indicative

FIGURE 4 Case C W

of postural disturbance, there is a fairly marked dorsal kyphosis. This case indicates how much of a dorsal kyphotic deformity can exist in a patient before treatment is undertaken. The strain during an induced convulsion, or rather repeatedly induced convulsions, would again be directed to the area of greatest curvature, namely the central dorsal vertebrae. So that were not some type of preventive measure undertaken one might almost visualize the area of subsequent compression during induced convulsions.

Figure 5 depicts our least severe injury (Case A C.) The interpretation is narrowing of the sixth dorsal vertebrae. If we compare this with the film (Fig 6) from another control (Case

D B), wherein the interpretation is narrowing of the disk between the first and second lumbar vertebrae, probably old, a definite mechanical predisposing factor can be made out

PREVENTIVE MEASURES

Perhaps the most outstanding and, to the orthopedist, most obvious factor with reference to vertebral compressions in the actual administration of the therapeutic convulsion is the manner

FIGURE 5 Case A C

in which the patient lies in bed at the time of the attack. As seen from Figure 7, the bed used in most state hospitals allows the patient to be suspended, so to speak, with the entire vertebral axis in an anteflexed position, which permits, if anything, an accentuation of any underlying, even mild, kyphosis. In a patient who is a little heavier than normal the vertebral column is proportionately more flexed. There is permitted more intimate contact of adjacent thoracic vertebrae. We, along with many other workers, have been accustomed to support firmly the shoulders and lower extremities during the reactions, by direct manual means as well as by the sheet bands already mentioned. Whereas this method prevents

excessive excursions of the limbs in any direction, it may possibly be an additive factor in causing vertebral compressions, in so far as the added weight of the attendant nurse promotes further sagging of the bed.

After careful consideration of the factors involved in the causation of mid-thoracic vertebral compressions, it was believed that orthopedically the most practical manner of preventing these injuries was to bring about hyperextension of the vertebral column, and at the same time prevent excessive intervertebral impingement at the time of the convulsion, in other words, to offset the lever advantage of the vertebral anteflexor muscles.

FIGURE 6 Case D B

The first measure employed was to place a specially constructed reinforced bolster under the patient's back so as to take up the sag of the bed, and to permit hyperextension of the spine by appropriate maneuvering. This method was workable, but it was found that a certain bolster did not comfortably fit all patients, and considerable maneuvering had to be done in many cases in order to obtain the necessary amount of hyperextension. In

other words, a bolster would have to be constructed for each patient, or else five or ten minutes would be consumed in properly applying this support before beginning treatment. This method also caused a certain amount of pretreatment apprehension, a feature that one must continually guard against in routine convulsive irritative therapy

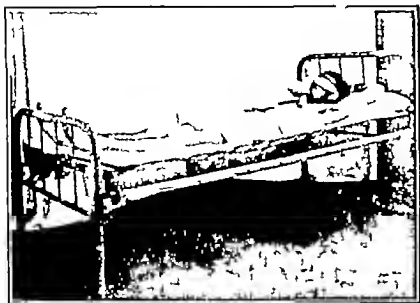

FIGURE 7

On inspection of the various uses of standard surgical beds, we observed that if the patient was put into the bed with his head toward its foot, the appliance on this bed ordinarily employed for elevating and flexing the knees was quite suit-

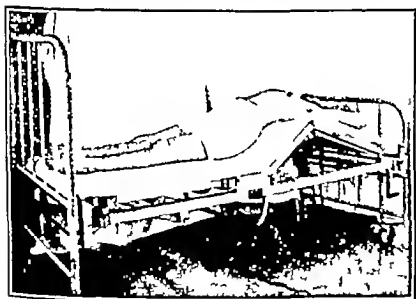

FIGURE 8

able for our purpose. There was thus available an easily adjustable frame that provided adequate hyperextension of practically the entire spinal column. It was further observed that by means of manual pressure at the shoulders and thighs during the convulsive reaction a maximum amount of intervertebral spacing was achieved. Figure 8 shows the application of the knee support of a standard surgical bed for purposes of hyperextension of the vertebral column. Figure 9 demonstrates the roentgenological evidence of dorsal hy-

perextension obtained by this method. This plate was taken with the patient lying on the support. During the treatment procedure, of course, the arms and thighs are held medially by means of sheet bands. The patient is placed in bed horizontally, the sheets are applied and the support is raised just prior to the administration of Metrazol. During the entire reaction the shoulders and thighs are firmly held down on each side of the mid-thoracic angulation by attendant nurses. In order to prevent over hyperextension of the cervical and lumbar vertebrae, a pillow is placed under the head and the hips are firmly pressed in a downward direction. Immediately after the reaction the support is lowered and the sheet bands are removed.

FIGURE 9

It has been noted that in each case where this method was employed an opisthotonic phase developed which tended even to increase the hyperextended vertebral position in which the patient was placed before the reaction. Up to the time of this report we had employed the above method in conducting the convulsive routine in the cases of 16 patients who had each undergone twenty grand mal reactions. Lateral lumbar and dorsal x-ray films taken before and after these courses of convulsive treatment revealed no cases of vertebral injury of any type. If one compares these courses of treatment with those of the patients mentioned in Table 1, the two may not appear equivalent. However as already demon-

strated by Polatin et al.,² compressions of the vertebrae may occur even after a single induced convulsive reaction, consequently it would be impossible for us to state with certainty when the compressions occurred with reference to the number of seizures undergone in the first group of patients

SUMMARY

1 Sixty-five chronically institutionalized psychotic patients were treated by an extensive regime of convulsive irritative therapy. It was found by routine x-ray studies of the dorsal and lumbar spines of all these patients that there had occurred 11 cases of single or multiple compressions of the vertebral bodies, all confined to the mid-dorsal region

2 None of the patients in whom vertebral compressions had occurred offered any localizing complaints, nor were any neurological or physical findings evident

3 No relation could be demonstrated between the occurrence of these compressions and the number and severity of the induced convulsions. With one exception, all patients were of the chronic sedentary, inactive type

4 Anatomical and orthopedic considerations of these findings led to the impression that certain mechanical predisposing and precipitating factors were present. Predisposing factors in the form of kyphoses, ruptured disks and even old compressions of the vertebral bodies were noted in 4 out of 13 control cases. Osseous porosity from disuse might also have been important, but the presence of this factor could not be proved. Precipitating factors were caused by the convulsive procedure per se. These consisted of sudden

flexor activities of the trunk musculature which predominated over simultaneous extensor movements because of the extreme leverage of the flexor group of muscles. The already fixed, flexed posture of the dorsal spine accentuated by the sag of the bed during treatment seemed to bring about a convergence of the intermittently acting muscle forces on the arched portion of the dorsal spine, wherein were found all the compression injuries

5 A workable, practical, preventive measure was demonstrated. This consists of employing the knee-support of the standard surgical bed as an adjustable vertebral hyperextension frame. This appliance seemed to prevent the occurrence of compression injuries to the vertebrae in a series of 16 consecutive cases

THE RELATION BETWEEN LEUKEMIA AND TUBERCULOSIS*

Report of a Case

HELMUTH ULRICH, M.D.,† AND HARRY PARKS, M.D.‡

BOSTON

EXAMINATION of the blood is usually the most important procedure in the diagnosis of leukemia. Occasionally, however, the hematologic findings may be misleading; leukemia may be present without typical hematological evidence if it (aleukemic leukemia), or leukemoid blood may be associated with other diseases, especially infections. In the case here reported, a picture typical of chronic myelogenous leukemia was present and led to that diagnosis. Miliary tuberculosis, which was found post mortem, had not been suspected.

The co-existence of leukemoid blood and tuberculosis, usually miliary, has been observed and reported by a number of authors. In a few cases the leukemia was of the lymphoid type; in the majority it was myeloid as in the present case.

CASE REPORT

M. P. G., a 45-year-old widow, entered the Massachusetts Memorial Hospitals on December 19, 1938, with weakness as the most prominent symptom. The family history revealed nothing of importance except that her husband had died of pulmonary tuberculosis in 1926, after they had been married 13 years. She had felt well until the preceding January when she began to tire easily and felt a pulling sensation in the left upper abdomen. Shortly afterward she noticed a lump in that region. She consulted her physician who found an enlarged spleen and made a diagnosis of chronic myelogenous leukemia on the basis of a white-cell count of 180,000 with 58 per cent myelocytes and young forms. Radiotherapy brought about improvement for a time, but later the weakness increased, fever developed, the lower extremities became edematous, and a skin eruption appeared and about 1 month before entering the hospital the patient was forced to give up her work as a cashier. About 1 week before admission she began to show signs of an upper-respiratory infection with cough, coryza and aggravation of all symptoms. She had lost 30 pounds in weight since the beginning of her illness.

Physical examination revealed pallor of the skin and evident loss of weight. Thickly scattered over both arms and legs were many discrete, slightly elevated nodular eruptions measuring 8 mm. in diameter with a central yellow area 3 mm. or less in diameter (Fig. 1). There was edema of both legs. The cervical lymph nodes were markedly enlarged, nontender and moderately fixed. A few enlarged nodes were present in the axillae and groins. Examination of the heart and lungs revealed nothing abnormal. The spleen was firm and nontender and extended

to the median line and to about 3 cm. below the level of the umbilicus. The temperature was 100.2 F. during her stay in the hospital; it varied between 97.0 and 103.2 F. Urinalysis and serological and chemical examinations of the blood gave normal results, with the exception of a low serum calcium (7.3 mg. per 100 cc.). The blood counts (Table 1) and stained films (Fig. 2) were typical of myelogenous leukemia.

Radiotherapy was administered and Fowler's solution was prescribed. Subjective improvement and a decrease

FIGURE 1 Maculopapular Eruption and Swelling of the Cervical Lymph Nodes

in the number of leukocytes followed. The patient left the hospital at the end of 3 weeks. She rested at home for 2 months and then felt well enough to resume her work.

Three weeks later she was readmitted because of weakness, cough, swelling of the abdomen and fever. Physical examination revealed more obvious loss of weight, increased pallor and abdominal distention. A thick post nasal discharge was present; the nasal mucosa was congested. The cervical lymph nodes, although still enlarged, were smaller than they had been at the previous examination. The cutaneous lesions had healed, but brownish spots remained. The ocular fundi were normal. A few scattered moist rales were heard throughout the chest, and

*From the Evans Memorial Massachusetts Memorial Hospitals, Boston.

there were diminution of breath sounds and dullness at the right base, suggestive of hydrothorax. The heart was normal. The distended abdomen was tympanitic except in the flanks and in the left upper quadrant, where there was flatness, evidently from an accumulation of fluid and an enlarged spleen. The splenic enlargement, however, was less marked than before, extending only 10 cm below

TABLE 1 Blood Leukocyte Counts and X-Ray Treatments

the left costal margin. Neurological examination revealed nothing abnormal. Radiography showed slight symmetrical cardiac enlargement and an old tuberculous calcification in the apex of the right lung. A plain film of the abdomen revealed nothing unusual except the splenomeg-

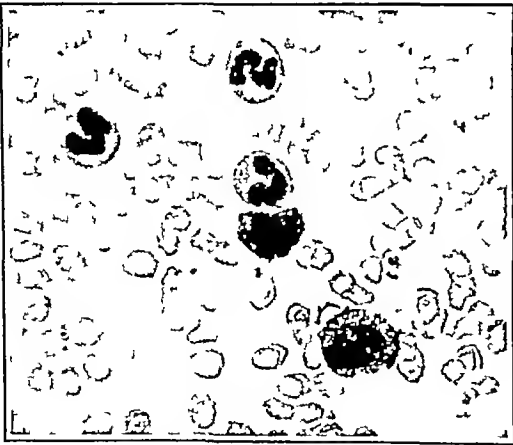

FIGURE 2 Myelocytes in Stained Film of Blood

aly. The electrocardiogram was not remarkable. The basal metabolic rate was +41 per cent. The diagnosis of myelogenous leukemia was accepted by several examiners. The patient gradually failed, finally became comatose and died May 9, 1939.

Autopsy. The peritoneal cavity contained about 8000 cc. of clear, amber fluid. Recently organized fibrous adhesions were found between the intestinal loops, omentum, liver, diaphragm, uterus and ovaries. The omentum was board-like in consistence and profusely studded with numerous small, slightly elevated, grayish-white, milium lesions about

1 mm in diameter. The visceral and parietal portions of the peritoneum presented similar lesions. The right pleural cavity contained 2000 cc. of clear, amber fluid. There were firm adhesions over an old healed calcified scar at the apex of the right lung. The left pleural cavity did not contain fluid but was obliterated by old fibrous adhesions. The spleen weighed 1180 gm. and measured 25 by 15 by 8 cm. Its surface was partially covered by adhesions and by a moderately thick, easily removable, pale yellowish-gray pad of fibrin. The surface of the liver presented a similar appearance. On the cut surface there were pinhead sized grayish spots that suggested myeloid accumulations. All the serous surfaces of the entire gastrointestinal tract, bladder and pelvic organs were studded with milium lesions similar to those found on the omentum. The sternal, vertebral and femoral bone marrows were grossly hyperplastic.

On microscopical examination acute milium tubercles

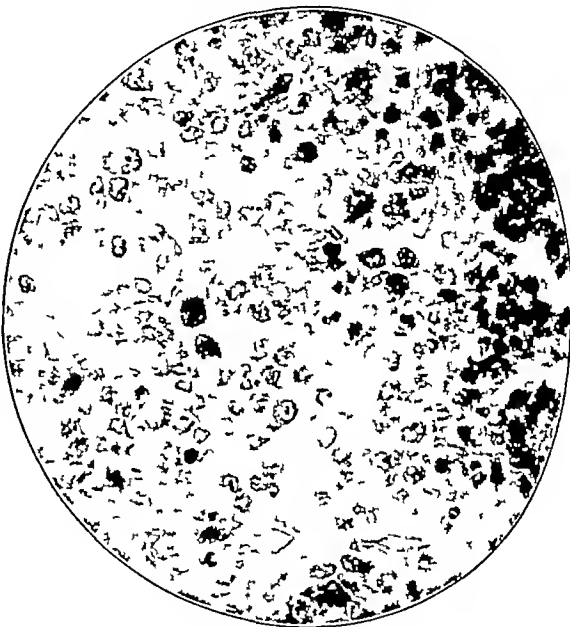

FIGURE 3 Myeloleukemic Infiltration in the Spleen

were found in certain portions of the lungs, with necrotic central areas surrounded by neutrophilic leukocytes, endothelial leukocytes and fibrin. Occasional areas of caseation were present on the capsule of the spleen, with peripheral zones of fibrous connective tissue, phagocytic endothelial cells and rare foreign body giant cells. Scattered throughout the substance of the spleen were many neutrophilic leukocytes, as well as immature forms of granulocytes (Fig 3). The capsule of the liver was covered with many young and moderately developed tubercles. Rare caseous foci were seen in the hepatic parenchyma. Around a few of the portal canals there were small accumulations of myeloid cells, but this was much less marked than is customarily the case in chronic myelogenous leukemia. The intestinal serosa was rather uniformly studded with young and moderately advanced milium tubercles (Fig 4). About the periphery of some of them small zones of leukemoid infiltration were seen. Acid fast bacilli were demonstrated. The mesenteric lymph nodes contained discrete and confluent areas of caseation, and in a few there was a suggestion of early leukemoid reaction. In the sternal, vertebral and femoral bone marrows there was complete replacement of the normal structure by massive accumula-

nons of immature myeloid cells, such as are characteristic of myelogenous leukemia (Fig. 5) Miliary tubercles were not found.

In 1849 Virchow¹ reported what was probably the first recognized case of this type. His patient had a large spleen which filled the whole left abdomen and weighed about 1500 gm. There were miliary tubercles in the pons varoli and in the lungs, pleurae, pericardium, liver and kidneys. Although at that time the methods of ex-

and fulminating miliary form of tuberculosis. The studies of Moreschi and others (quoted by Forkner²) showed that the production of antibodies and the phagocytic activity are diminished in leukemia. Jaffé³ also found that immature leukocytes are deficient in defensive properties.

Susmann,⁴ who believed that the two diseases may exist together, postulated three possible combinations: the tuberculosis is latent and is not affected by the subsequently developing leukemia, it is latent and is activated by the leukemia (this is commonest), it supervenes as a terminal infection.

The fact that leukemic infiltration of the internal organs was lacking in the majority of the cases of combined leukemia and tuberculosis has been used as evidence that the blood picture was leukemoid only and not the result of the disease,

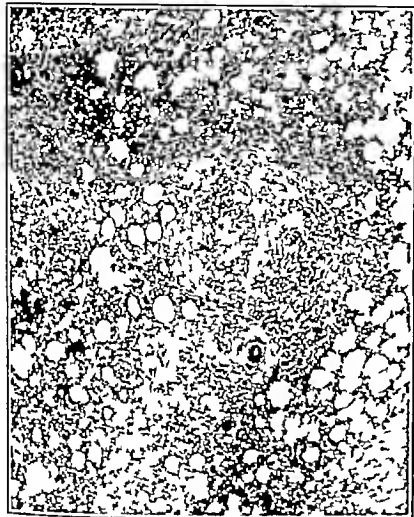

FIGURE 4 Miliary Tubercle in the Wall of the Intestine

amining the blood were in an undeveloped stage, the description of the findings leaves little doubt that the blood was leukemoid in character.

The nature of the relation between leukemia and tuberculosis has puzzled nearly everyone who has observed their association in the same patient. Some authorities have believed that the leukemoid character of the blood is an unusual response of the leukopoietic tissues to the tuberculous infection and not true leukemia, others have maintained that in many cases one disease was complicated by the subsequent or previous occurrence of the other. The fact that in the majority of cases the tuberculosis is of the miliary type may be used as evidence for either conception; that is, leukemoid reactions may occur especially in miliary infections; on the other hand, the lowered resistance assumed to be present in leukemia may permit the development of an acute

FIGURE 5 Myeloleukemic Changes in the Bone Marrow

leukemia. Support for this contention is supplied by results obtained in the experiments of Feldman and Stasney.⁵ They found that rabbits sensitized with tubercle bacilli responded with leukocytosis (up to 124,000 in an animal) to injections of Old Tuberculin, the reaction resembling the so-called "leukemoid reaction" described in human beings. The reactions, however, were of but short duration, lasting only four days or less. The authors assumed that "since the majority of leuke-

CLINICAL NOTE

SYSTEMIC AND LOCAL REACTIONS
TO EPINEPHRINE IN OIL

ANGELO L. MAIETTA M.D.*

WINCHESTER MASSACHUSETTS

WITH the introduction of epinephrine in oil by Keeney¹ in 1938, the symptomatic treatment of allergic conditions, particularly asthmatic seizures and intractable asthma, has acquired a new impetus. The material can be obtained commercially in ampules, each containing 2.0 mg epinephrine crystals in peanut oil. Since its introduction, this preparation has been employed with increasing frequency by the general practitioner, as well as by the specialist in allergic diseases. Although epinephrine in oil is a valuable therapeutic weapon, the physician should be cognizant of its frequent untoward results that may follow its use. Murphy and Jones² presented a series of 9 cases in which epinephrine in oil was employed. These authors note in 1 patient untoward systemic reactions characterized by nervousness, insomnia, palpitation, nausea vomiting and headache. No local manifestations were observed. Cohn³ reports 4 cases in which epinephrine in oil was used with the following unusual symptoms: nausea, vomiting, dizziness, vesicular urticaria, cyanosis, increased dyspnea and local edema.

Since its introduction I have employed this preparation on 14 patients who did not respond to the usual measures. All these patients were markedly benefited. However, with 2 of them there were untoward reactions each time the preparation was injected. In one, systemic symptoms, such as cold hands and feet, chilly sensations, clammy perspiration, facial pallor, frontal headache and cardiac palpitation; in the other, local manifestations characterized by a preliminary blanching followed by redness, intense itching, marked edema and inflammation at the site of the injection. The routine of administration was as follows: 10 cc. of epinephrine hydrochloride solution (1:1000) was injected subcutaneously, followed with ten minutes with 1 cc. of sterile peanut oil containing 2.0 mg of epinephrine injected intramuscularly, the plunger of the syringe always being pulled back before injection, in order to be certain that the preparation was being injected directly into the muscle and not into a blood vessel.

CASE REPORTS

CASE 1. J. B., a 37-year-old man, had suffered from bronchial asthma for the previous 18 years. History and tests revealed that the patient was sensitive to both pollen and bacterial products. He was continuously dyspneic. His asthmatic seizures were severe and lasted for 72 hours occasionally even for more than a week, after which symptoms would clear completely only to return within

a few days with a renewed intensity. During these episodes, the patient administered to himself adrenalin chloride vapor (1:100) at very frequent intervals. Oxygen inhalation was resorted to frequently and 0.5 to 1.0 cc. of adrenalin chloride 1:1000 was subcutaneously injected every one or two hours.

When first seen the patient was having a very severe asthmatic seizure, which had failed to respond to the above self-administered measures. Four tenths of a cubic centimeter of epinephrine hydrochloride (1:1000) was injected subcutaneously. This was immediately followed by an injection of 1/75 gr of atropin sulfate. Shortly afterward the dyspnea began to abate. Ten minutes later an intramuscular injection of epinephrine in oil was given. Within a few minutes the patient complained of feeling chilly. His hands and feet became cold. This was followed by a clammy perspiration and a moderately intense facial pallor. At this time the patient complained of frontal headache and palpitation. These symptoms, which lasted about 1½ hours, were treated by external heat and brandy by mouth. Subsequently on four other occasions it became necessary to repeat the administration of epinephrine in oil, and each time the above train of symptoms appeared. The asthmatic symptoms, however for the relief of which the epinephrine in oil was administered, were greatly ameliorated.

CASE 2. D. F., a 38-year-old, obese woman, had had bronchial asthma from ragweed pollen for the previous 12 years.

When first seen the patient was having a severe asthmatic attack. Four tenths of a cubic centimeter of epinephrine hydrochloride was administered subcutaneously followed within ten minutes by an intramuscular injection of epinephrine in oil deep into the deltoid muscle. Within 1 hour marked blanching appeared at the site of the injection. This was replaced slowly by an intense redness, which spread over the shoulder, down the arm and well into the forearm. At the same time, the involved area became markedly edematous and greatly indurated and was very itchy. These symptoms continued for 24 hours and then began to recede. At the end of 6 days the arm had returned to normal. The local reaction was treated with ice packs and cold boric acid compresses. On two other occasions when it became necessary to administer epinephrine in oil the same train of symptoms appeared, the only variation being that the reactions from the second and third injections lasted 7 and 8 days, respectively. Notwithstanding these untoward local manifestations, the asthmatic symptoms were promptly controlled for a prolonged period of time.

SUMMARY

Epinephrine in oil plays an important part in the symptomatic relief of allergic states.

Its administration is not harmless, for complicating symptoms that are transitory can develop following its use.

The infrequency with which these untoward symptoms occur does not preclude the judicious administration of epinephrine in oil.

Two cases are presented in which the use of epinephrine in oil for symptomatic relief of severe asthma was followed by unusual systemic and local symptoms.

REPORT ON MEDICAL PROGRESS

OPHTHALMOLOGY

DAVID G. COGAN, M.D.*

BOSTON

DURING the past year there has been no spectacular progress in ophthalmology. This report deals with a few selected ophthalmological subjects that have attracted attention in recent years. They have been selected on the basis of general interest.

VITAMIN A

The recent clinical and laboratory developments in the field of vitamin A have centered about the eye. Not only are the outstanding clinical manifestations of vitamin A deficiency ocular, but there is considerable evidence that in the normal state the vitamin A molecule is involved in the visual process taking place in the retina.

Ocular disturbances due to vitamin A insufficiency are of two distinct types. The one involves primarily the epithelium of the cornea, conjunctiva and lacrimal apparatus, and its several clinical manifestations are grouped under the heading of xerophthalmia. The other involves the retinal process concerned with vision, particularly in low illumination, and its clinical manifestation, in the form of poor dark adaptability, is called hemeralopia.

Xerophthalmia is the ocular counterpart of the general mucous-membrane disturbance that occurs in vitamin A deficiency.¹ Like the keratinization of the pulmonary bronchioles, which makes the vitamin-A-deficient patient susceptible to pneumonia,² and like the keratinization of the urinary tracts, which gives rise to excessive numbers of epithelial cells in the urine and possibly to renal lithiasis,³⁻⁵ there is keratinization of the corneal and conjunctival epithelium. In the milder forms, xerophthalmia imparts a dry appearance to the eye, and foamy deposits (Bitôt spots) made up of keratinized epithelial cells and saprophytic organisms (*Corynebacterium xerosis*) may appear on the conjunctiva.^{6,7} In the severer form, called keratomalacia, the entire cornea may disintegrate.

Fortunately, xerophthalmia is not common in this country, where the nutrition of the population is good, but it is common in the Far East, and has occurred epidemically abroad at times of limited food supply.^{8,9} Its occurrence in this

country is usually in infants, perhaps owing to greater need for this vitamin during growth.¹⁰

However, several recent observations indicate that the development of xerophthalmia is not dependent solely on vitamin A deficiency. It has been found, for instance,¹¹ that excess of vitamin D causes typical xerophthalmia, even in the presence of normal vitamin A intake. It has been shown experimentally that excess of sodium chloride with a vitamin B deficit in the diet may produce keratomalacia.¹² There is evidence also that damage to the liver by phosphorus may predispose to the development of xerophthalmia.¹³ Calcium deficiency has a similar effect.¹⁴

There appears to be no good evidence that keratoconus in human beings is the result of vitamin A deficiency, although it may occur in animals recovering from xerophthalmia.^{15,16} There is some evidence, based on the experimental work of Heinsius,¹⁷ that corneal abrasions heal more rapidly when vitamin A is used locally on the eye. Kentgens¹⁸ reports finding a low vitamin A content in the serum of patients with various corneal diseases.

The other ocular manifestation of vitamin A deficiency, hemeralopia, is attracting a great deal of interest both in the biological laboratories and in the clinics. It has been known for some time that vitamin A deficiency is characterized by relative inability of the eye to adapt to conditions of low illumination.^{19,20} It has also been shown that the process of dark adaptation is accompanied by, and is probably dependent on, the formation in the retina of a photosensitive substance called visual purple. In the absence of vitamin A the amount of visual purple formed in the retina is subnormal.^{21,22} It has been suggested by Wald²³ that visual purple is, in fact, derived directly from vitamin A. In favor of this is the presence in the retina of large amounts of vitamin A.²⁴⁻²⁶ One must admit, however, that although the chemical formula for vitamin A is known, that for visual purple is as yet unknown.

From the clinical point of view, the fact that vitamin A deficiency is characterized by poor dark adaptation is important, since this function can be measured. The several instruments for measuring it have in common the routine of exposure to a bright light for a known period, and subsequent

*Assistant in ophthalmology, Harvard Medical School; assistant surgeon, Massachusetts Eye and Ear Infirmary; assistant in ophthalmic research, Howe Laboratory of Ophthalmology, Boston.

determinations of the light thresholds over a period of at least ten to fifteen minutes.²⁷ It is probably true that the difficulties inherent in the technic are not generally realized.²⁸ Defects in dark adaptation are said to reveal vitamin A deficiency before the patient has any subjective complaint.²⁹ Jeghers³⁰ claims to have shown by this means that subclinical vitamin A deficiency is present in a surprisingly large proportion of students. Jeans³¹ found subclinical hemeralopia in about one fifth of the children entering the pediatric ward in an Iowa City hospital. However, it is by no means certain that the findings with the biophotometer, the instrument used by Jeans and Jeghers, constitute a reliable index of vitamin A adequacy. Not only is the apparatus subject to large errors, but no norm has yet been established with it.³¹⁻³⁴ There are such wide variations of dark adaptation among normal individuals that it is unsafe in the present state of knowledge to diagnose vitamin A deficiency on the basis of this test alone.

Like xerophthalmia, frank hemeralopia in human beings has occurred epidemically when the food supply has been limited.³⁵ It also occurs occasionally with diseases of the liver,³⁶⁻³⁸ owing presumably to failure of conversion of dietary carotene into vitamin A, which normally takes place in this organ. There are a number of other conditions associated with poor dark adaptation which are not known to be dependent on faulty vitamin A metabolism.

Although hypervitaminosis A probably does not occur with the dietary surplus usually taken by human subjects, it is interesting that exophthalmos may be produced in rats with very large doses.³⁹ In these animals there is also concomitant enlargement of the thyroid gland.

OTHER VITAMINS

There is considerable recent literature pertaining to the role of vitamins B₁ and B₂ in ophthalmology,⁴⁰ but one cannot as yet derive any clear cut conclusions as to their significance for the human eye. On the clinical side it has been pointed out that retrobulbar neuritis is occasionally seen with beriberi,⁴¹⁻⁴² and this has led to the therapeutic use of thiamin chloride in all types of retrobulbar neuritis. It is also pointed out that defects in the central visual field are seen with pellagra,⁴³ especially with so-called alcoholic pellagra, and this has given rise to the use of nicotinic acid in alcohol-tobacco amblyopia. The therapeutic results have apparently been successful, but in the absence of other signs and symptoms of vitamin B lack neither the usual retrobulbar neuritis

nor the alcohol-tobacco amblyopia can as yet be classified as a vitamin deficiency.⁴⁴

On the nonclinical side, it is of interest that in many species of animals the retina is especially rich in lactoflavin,⁴⁵ one constituent of the vitamin B₂ complex. Lactoflavin is a photosensitive substance,⁴⁶ and it has been suggested that it may participate in the visual process, specifically in the reception of the short wave lengths of light. If this proves to be true, it may be found that this substance is analogous to visual purple.

Vitamin C is found in extraordinarily large amounts in the intraocular fluid⁴⁷ and in the lens⁴⁸ of the eye. It undoubtedly plays an important part in ocular metabolism. That it is vital to the lens is suggested by the fact that it is found to be markedly decreased when the lens is cataractous⁴⁹ or has been removed.⁴⁷ The therapeutic use of vitamin C to arrest cataract formation, however, has not been successful, and this form of treatment has now been abandoned. The decrease of vitamin C would appear to be secondary to the cataract formation, rather than the cause of it.

Deficiencies in vitamins D and E produce no proved ophthalmic lesions in human beings. It is claimed, however, that vitamin D deficiency and a low-calcium diet will produce keratoconus or an analogous condition in dogs and rats.⁴⁹ The treatment of progressive myopia with vitamin D has been as disappointing as other forms of treatment in this condition.⁵⁰

The effect of vitamin K in the treatment of retinal hemorrhages is being currently studied in various clinics, but no comprehensive report of the results is as yet available.

CONTACT GLASSES

Contact glasses are thin shells of glass which may be placed directly on the eyeball and thereby be made to provide an artificial refractive surface. Their chief purpose is to replace the refraction of a distorted corneal surface, but they may also be used cosmetically as a substitute for ordinary glasses.

The principle of contact glasses is not new. A contact device for replacing the corneal surface was suggested by Thomas Young⁵¹ in 1801. It was the logical outcome of his discovery that many visual errors were due to abnormalities of this surface. The accelerated interest in contact glasses during the last few years is due to certain technical advances in their fitting and manufacture which have made the glasses extensively applicable.

Until recently, contact glasses have been made exclusively of glass. They are now manufactured

in this country from plastic as well.* The glass type, which is still the commonest, is either blown or ground. The blown glass is better tolerated by the eye, but almost always contains some optical imperfections. Perhaps a device having the central optical part ground, or at least molded, and the peripheral part blown will be the happy compromise.⁵² The plastic type of contact glass has not been in use long enough to allow proper evaluation.

The fitting of a contact glass is not easy.⁵³ Strange as it may seem, the portion of the glass that fits over the sclera is more important, so far as the patient's comfort is concerned, than the portion that fits over the cornea.⁵⁴ Unfortunately, it is the scleral part of the eye that is asymmetric and variable with individuals. Hence, many glasses have to be tried before a properly fitting one is found. Inasmuch as stock glasses may therefore offer considerable difficulty, it has been the practice of some clinics during the last few years to make preliminary molds of the eye with dental composition, and to have glasses specially made to fit the molds.⁵⁴ ⁵⁵ Once a glass is properly fitted, it may be worn for a good part of the day without appreciable discomfort.

The indications for contact glasses are limited.⁵⁶ The two outstanding conditions calling for them are keratoconus and irregular astigmatism, in both of which there is a deformation of the cornea that cannot be corrected by ordinary glasses. Another generally admitted indication for contact glasses is high myopia. In this condition contact glasses have definite optical and cosmetic advantages over the ordinary type. There are a host of other possible uses, such as monocular aphakia⁵⁷ or as substitutes for regular glasses during certain athletics in which the danger of injury to the eye is less with the former than with the latter.⁵⁸ The chief disadvantages of contact glasses are their expense and the fact that they cannot be worn for long periods.

Like most other recent advances, that connected with contact glasses has its quota of overenthusiastic advocates. With full appreciation for the value of these glasses, it would seem that there is hardly sufficient basis for advertising claims such as that which appeared in a recent Boston circular: "Eyeglasses in frames are obsolete — use contact lenses."⁵⁹

EXOPHTHALMOS AND THYROID DISEASE

Two new approaches to the problem of exophthalmos with thyroid disease have yielded profitable results. One, which might be called the therapeutic approach, is Naffziger's operation of orbital

decompression for exophthalmos of high degree, the other, coming from the laboratories, is the experimental production in animals of a condition similar to, if not identical with, certain types of exophthalmos in human subjects.

Until recently it has been customary to consider exophthalmos a manifestation of hyperthyroidism, having essentially the same pathogenesis, whatever that may be, in all cases. It has, however, been observed frequently that the degree of exophthalmos is not commensurate with the amount of hyperthyroidism. It has been particularly noted that the severest cases of exophthalmos, the so-called malignant or progressive type, are especially liable to show little or no other evidence of hyperthyroidism, so that the latter alone cannot be held accountable in these cases. It is with progressive exophthalmos that recent progress is concerned.

In 1931 Naffziger devised the operation of orbital decompression for progressive exophthalmos. He at first advocated removing only the roof of the orbit and of the optic canal. More recently he⁶⁰ has advocated the removal of some of the lateral orbital wall as well. Although this is obviously a major procedure, it is generally accepted as the operation of choice when loss of the eyes through exposure is imminent. Progressive exophthalmos is not amenable to the usual treatment of hyperthyroidism. Iodination has no effect, and thyroidectomy often makes the condition worse. Naffziger's operation is therefore the only alternative in many cases. Immediately after it the exophthalmos is worse, but recession of the globe takes place gradually over a period of several months thereafter.

The widespread employment of orbital decompression in progressive exophthalmos has resulted in a fairly large amount of pathologic material becoming available for study. Naffziger and Jones's⁶¹ original findings based on biopsies of the extraocular muscles have been repeatedly confirmed.⁶²⁻⁶⁶ There is a characteristic "proliferation" of round cells, interstitial edema and a Zenker type of degeneration of the muscle fibers.⁶⁷ Naffziger believed that the increase in size of the extraocular muscles is alone responsible for the exophthalmos, but it is not evident that he examined other orbital tissues, and more recent studies by others⁶⁸ indicate that the extraocular muscles are only part of a generalized orbital infiltration.

As regards the other source of information, that from the laboratories, a few years ago it was found that injections of anterior pituitary extract in the young duck caused exophthalmos.⁶⁹ It was then

*Made by Gall and Lembke, 7 East 48th Street, New York City.

ried on guinea pigs and other mammals,^{68, 70-72} with the result that a lasting exophthalmos was usually produced. Preliminary removal of the thyroid gland^{73, 74} favored its development. The fraction of the anterior pituitary gland responsible for the exophthalmos is apparently the thyrotropic hormone. Removal of the thyroid gland increases the amount of thyrotropic hormone in the pituitary gland⁷⁴ and thus enhances the exophthalmos-producing potentialities. The exophthalmos produced by the injection of this hormone is the experimental counterpart of progressive exophthalmos in human beings. The histologic changes in the orbit are the same.⁶⁸ Both experimental and clinical exophthalmos are more apt to develop following thyroidectomy. Hyperthyroidism, far from being essential, appears to be actually inhibitory to this type of exophthalmos, for the latter does not develop until the basal metabolic rate has been lowered to nearly normal or to subnormal levels. The clinical use of iodine and thyroxin in the treatment of this type of exophthalmos has, however, been disappointing,^{75, 76} although in massive doses thyroxin does have a beneficial effect on experimental exophthalmos. *Inasmuch as the doses are near lethal levels, it would be out of the question to use similar amounts in human subjects.*

Other glands of internal secretion may affect the exophthalmos either directly or indirectly through the pituitary gland. Exophthalmos is relatively unusual after the decline of sexual life, and Marne⁷⁷ reports that gonadectomy prevents experimental exophthalmos in rabbits, while injections of the androgens hasten its appearance. The female sex hormones do not appear to have the same exophthalmos-producing properties that the male hormones have.

The most comprehensive recent review of exophthalmos in connection with thyroid disturbances is that of Brain and Turnbull.⁶⁶ These authors differentiate exophthalmic goiter and what they call exophthalmic ophthalmoplegia. The former is Graves's disease, and the latter is what is generally called in this country progressive or malignant exophthalmos. They list the following distinguishing features. Women are affected predominantly in exophthalmic goiter in a ratio of 9:1 whereas in exophthalmic ophthalmoplegia the sexes are about equally affected. The thyrotoxic symptoms and signs other than the exophthalmos are relatively conspicuous in exophthalmic goiter, whereas they are usually slight or absent in exophthalmic ophthalmoplegia. Indeed in the latter condition there may be hypothyroidism. The usual initial symptom in exophthalmic goiter is nervousness, loss of weight or tremor, whereas the first and frequently the only complaint in exophthalmic ophthalmoplegia is the exophthalmos.

Patients with exophthalmic goiter are benefited by iodine and thyroidectomy, while those with exophthalmic ophthalmoplegia show no improvement with iodine and are frequently made worse by thyroidectomy. The response to treatment on the one hand and lack of response on the other may also differentiate the myopathy that occurs in the two conditions. The amount of exophthalmos is greater in exophthalmic ophthalmoplegia, being on an average 7.0 mm., in comparison with 2.5 mm. in exophthalmic goiter. The rate at which the exophthalmos develops is also more rapid in exophthalmic ophthalmoplegia. For the cause in the latter condition Brain and Turnbull accept the thyrotropic hormone theory.

While considerable progress has thus been made in understanding the cases that develop exophthalmos with little other evidence of hyperthyroidism, the mechanism of exophthalmos in Graves's disease is still a mystery. A recent editorial⁷⁸ in the *Journal of the American Medical Association* probably represents a majority opinion by unqualifiedly accepting the explanation that the exophthalmos results from sympathetic stimulation. The basis for this belief is of course the fact that exophthalmos may be produced in animals by stimulating the cervical sympathetic chain.⁷⁹⁻⁸⁰ But this has not been found to be the case in human beings, and Whitnall⁸¹ denies that there is sufficient smooth muscle in the human orbit to have any appreciable effect. Furthermore, the pupil, which is ordinarily the most sensitive indicator of sympathetic activity,⁸² shows no evidence of stimulation in Graves's disease.⁸³ Nor has sympathetomy had any beneficial effect on the exophthalmos.⁸⁴ It would seem wise, therefore, to reserve judgment as to the cause of exophthalmos in Graves's disease until more evidence is available. Fortunately it does not present the clinical problem that progressive exophthalmos does, as it usually yields to adequate therapy of the hyperthyroidism.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTHEMORTUM AND POSTMORTUM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26171

PRESENTATION OF CASE

A twenty-three year-old man was admitted to the hospital complaining of intermittent cough and hemoptysis.

The patient had been well until six and a half years before admission, when he began coughing while eating sugar-coated cookies. He raised about a teaspoonful of mucoid sputum which "contained blood." Following this he noted a tickling sensation in the throat for several days, although he did not cough. A few months later he developed a severe cough, with sputum and fever that lasted about ten days. A similar attack occurred one month later, but there was no hemoptysis at either time.

About five years before entry similar symptoms reappeared, with the production of moderate amounts of yellowish mucoid sputum. He had "pleurisy" on the left side and was admitted to an outside hospital, where roentgenograms of the chest showed "some density in the left upper lobe." Bronchoscopy was performed, and following this the patient raised copious amounts of yellow, mucoid, odorless sputum for several days. Then the cough and sputum subsided. He was well and entirely symptom free for the next one and a half years. He steadily gained weight and led a normal vigorous life, except for the fact that throughout this interval he was subjected to repeated diagnostic bronchoscopies at least once every two months.

Four months before admission he again developed fever and a cough with the raising of yellow, mucoid sputum, for which he was readmitted to the same hospital. Repeated therapeutic bronchoscopies were of little aid, however, and calcium and atropine tablets relieved his symptoms. He was discharged from the hospital without a definite diagnosis. The repeated bronchoscopies were continued about once every four months for the next two years. He felt well, working as a salesman and later as a golf professional. Two years before admission he noticed that he tired easily and that he was losing weight. Artificial pneumothorax was tried as a therapeutic procedure. He then felt much improved, but about two months after

ward again had a typical attack of fever and cough, with the production of yellow, mucoid sputum.

X ray films of the chest showed fluid at the left base." He was ill ten days and following this was well for months, although the bronchoscopies were regularly repeated and the pneumothorax was continued by refills. One and a quarter years before admission he awoke one morning and coughed up a mouthful of pure, bright red blood. The sputum was blood streaked for several days thereafter, but he felt well until one year before entry when an identical attack of hemoptysis occurred, followed by a "streptococcal sore throat" lasting two weeks. He had a temperature of 103°F, he was nauseated and vomited frequently, and the productive cough recurred. He sometimes raised as much as two cupfuls of yellowish sputum daily. He was hospitalized for seven weeks. Since that time he had never been free of symptoms, the cough with sputum persisting until the present admission, although it was sometimes relieved by dependent drainage. He continued to have pneumothorax refills until six months before entry, although without much relief.

Three months before admission he again coughed up a mouthful of bright-red blood. For three weeks thereafter the sputum was blood streaked. Since then he had had six similar attacks, the last occurring four days before entry. During the year preceding entry the patient experienced a slow but steadily increasing dyspnea on exertion. He lost no weight, although he failed to gain. Throughout the course of the six year sickness, bronchoscopy was performed sixty five times. All specimens removed at biopsy were negative. The family and past histories were negative. He entered this hospital for surgical treatment.

Physical examination revealed a fairly well developed and rather poorly nourished man who lay in bed in no acute distress. He coughed at irregular intervals, raising thick, yellowish mucopurulent, odorless sputum. The right chest was definitely larger and more expansile than was the left. Tactile fremitus was diminished, and almost the entire left chest was dull to flat. Over the same area the breath sounds, vocal fremitus and whispered voice sounds were diminished to absent. No wheeze or rales were noted. There was obvious clubbing of the fingers. The heart was negative; the blood pressure was 138 systolic, 80 diastolic. The remainder of the physical examination was negative.

The temperature, pulse and respirations were normal.

Examination of the blood showed a red-cell count of 3,700,000 with 80 per cent hemoglobin, and a white-cell count of 13,200 with 87 per cent poly

morphonuclears The urine was negative The sputum was mucopurulent, contained cocci in chains, but no spirochetes or acid-fast bacilli A sputum culture showed a moderate growth of beta-hemolytic streptococci The basal metabolism was +5 per cent A glucose tolerance test and the serum calcium, phosphorus and phosphatase levels were all normal

Roentgenograms of the chest showed consolidation involving the left upper lobe as well as the anterior portion of the left lower lobe, with multiple cavity formation in the same areas The heart was slightly displaced to the left and showed an inspiratory shift to the left The right half of the diaphragm showed normal motion, the left was not clearly visible The right lung showed no significant abnormalities Films of the hands showed an increase of soft tissues, there was no evidence of periosteal new-bone formation

The patient remained in the hospital under observation for ten days On the eleventh day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR FREDERICK T LORD May we see the x-ray films?

DR AUBREY O HAMPTON The right lung is normal There are cavities from the apex to the diaphragm on the left side, most of them are apparently in the upper lobe and contain fluid levels The pleura is thickened over the entire left side, and the left side of the diaphragm is two interspaces higher than normal The mediastinum has shifted a little to the left in the upper portion, and a little to the right in the lower portion

DR LORD Is there anything unusual about the bronchi?

DR HAMPTON I do not see a localized area of fibrosed lung such as you see in chronic bronchiectasis, but there are so many lesions in the lung that it might be obscured Here there is a suggestion of a localized patch of dilated bronchi in the middle of the left lower lobe

DR LORD We have a twenty-three-year-old man with six and a half years' disturbance of a respiratory nature, which was at first intermittent and during the past year continuous For the first four or five years he had complete freedom between the attacks of cough, fever and sputum During the past year he expectorated a large amount of odorless, purulent sputum, and had shortness of breath and moderate hemoptysis

The physical signs—dullness to flatness, with diminished breath sounds, tactile fremitus and whispered voice sounds—are very suggestive of bronchial obstruction However, they are not distinctive of it, so that one cannot draw the con-

clusion that he had bronchial obstruction from the signs alone Similar signs are found in other conditions tumor would produce the same signs, as would multiple cysts not communicating with the bronchi He had a moderate secondary anemia

I should like to know more about the sputum, the record gives little of significance One of the more interesting parts of this story is the large number of bronchoscopic examinations, and I must say that a striking feature about them is that while the record mentions them many times, it says nothing about the findings

DR RALPH ADAMS He was bronchoscoped in an effort to make a diagnosis

DR LORD In an outside hospital?

DR ADAMS Yes, in fact by an expert bronchoscopist of whose competence there can be no doubt When he came to Boston the diagnosis remained unestablished

DR LORD From the bronchoscopic point of view?

DR ADAMS Yes

DR LORD That does not help much

Of course, x-ray study is of great importance in trying to unravel the situation I should like to know what the x-ray film taken five years ago showed

DR ADAMS It showed an increased density on the left side of the chest

DR LORD That is what the record says With so many pathologic changes now, it might help to unravel the problem if we knew what he had five years ago

DR ADAMS They suspected cancer

DR LORD It would be desirable to know more about the sputum Perhaps it is fair to assume that other examinations were made Tuberculin tests, if necessary up to and including 1 mg of tuberculin, would be desirable, and also a search of the sputum many times for tubercle bacilli and such other investigations as concentration and culture of the sputum and examination of the gastric contents for tubercle bacilli

DR BENJAMIN CASTLEMAN All that had been done prior to entry, but nothing was found

DR LORD According to the x-ray film there is no special suggestion of tuberculosis in the upper part of the chest there is no finely or coarsely mottled increase of density above the anterior portion of the third rib extending out to the periphery The use of Lipiodol is an investigation to be considered under these circumstances, but it is questionable as to whether we should get any valuable information out of it

To come to a conclusion with respect to this problem, I make the diagnosis of chronic pulmo-

nary suppuration with confidence, but I am not so sanguine about unraveling the cause.

I am inclined to exclude tuberculosis. Dermoid cyst seems highly improbable with such a diffuse process.

Bronchial obstruction cannot be excluded but with the lack of detailed information regarding the bronchoscopic findings it cannot be concluded that he had bronchial obstruction. There is the possibility that at the time he coughed while eating cookies, he inhaled a foreign body with consequent bronchial occlusion and infection beyond the obstruction. A bronchial tumor is another possibility, but with the bronchoscope in competent hands, it is difficult to understand how a tumor in accessible bronchus could be missed. A tumor in the lung itself, invisible by bronchoscopy, is a possibility. Such a tumor would be likely to be of a benign type, as evidenced by the duration of the illness and his good general condition at the time of entry. I have to leave the question of bronchial obstruction without reaching any definite conclusion.

There is evidence of multiple cavities containing purulent material. Owing to the absence of foul sputum, they are unlike the commonest type of lung abscess, and they may have been caused by bronchial obstruction and consequent infection with resulting abscesses, induration and bronchiectasis.

There is another possibility that cannot be excluded, namely congenital cystic disease, which is probably commoner than we have appreciated.

I shall have to make a diagnosis of chronic bronchopulmonary suppuration of undetermined origin, but with such underlying factors as I have suggested as possible causes.

DR. CASTLEMAN: Dr. Churchill, do you remember what your preoperative diagnosis was?

DR. EDWARD D. CHURCHILL: It was bronchial obstruction due to inflammatory stricture or benign tumor. The bronchoscopist who had performed the innumerable bronchoscopies always said that there was a tumor there although he could not reach it.

DR. LORD: Or see it?

DR. CHURCHILL: He saw only a blind ending of the upper lobe bronchus on that side.

The operation was a total pneumonectomy. We knew we had to find some solution for these recurrent life-endangering episodes of infection. His physician was very anxious about the delay that was necessary to get him on the waiting list, because he was so afraid that the young man would have another very serious episode of infection.

At operation the primary lesion was not evident

at first, not until the operation was nearly completed. The apex was adherent, so much so that in dissecting it out the question was raised in my own mind whether we were dealing with bronchial stricture of tuberculous origin, but when I finally had mobilized the lung and reached the hilar region I could feel a round tumor and hence carried the amputation of the lung to a level proximal to the tumor.

CLINICAL DIAGNOSIS

Bronchial obstruction due to inflammatory stricture or benign tumor

DR. LORD'S DIAGNOSIS

Chronic bronchopulmonary suppuration of undetermined origin

ANATOMICAL DIAGNOSES

Bronchial adenoma

Bronchiectasis.

Chronic pneumonitis.

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The hilar mass that Dr. Churchill was able to feel at operation was a hard nodular tumor about 2.5 cm. in diameter, which at first glance appeared entirely extrinsic to the main left upper lobe bronchus but fairly adherent to it. Further examination disclosed that this tumor was an extension of a small intrabronchial non-occluding lesion. In other words, the larger extrinsic portion of the tumor had produced by pressure the bronchial obstruction that had prevented the bronchoscopist from seeing or biopsying the lesion. The cut surface of the lung showed that the upper lobe was completely atelectatic and composed of distended bronchial cavities with a superimposed chronic pneumonitis. The tumor had produced obstruction to one of the bronchi to the lower lobe, and the portion of the lung supplied by this bronchus was similarly involved.

Histologically the tumor is a so-called "adenoma," being composed of small round cells usually arranged in pseudo-acinar formation, definitely invasive locally, and in our experience not malignant. Out of about 20 cases that we have seen only one showed a metastasis to a regional lymph node. Although they are very similar microscopically to the carcinoids of the small intestine, we have never been able to prove that they are argentaffin. In spite of these negative findings Hamperl¹ still believes that they belong in the same group with the carcinoids, although Womack and Graham,² of St. Louis, contend that they fit in with their classification of mixed tumors of the lung.

DR. ADAMS The bronchoscopist's observations throughout the repeated bronchoscopies had been correct, although he could not arrive at a diagnosis. He would look down and see occlusion of the bronchus, and take a biopsy of the hard mass, only to get a report of bronchial mucosa. The bronchial obstruction visible by bronchoscopy was caused by extrinsic pressure from tumor that had grown downward into the hilus, from its origin in a peripheral bronchus.

DR. CHURCHILL The importance of this tumor at the moment lies in the confusion that exists between it and true bronchiogenic carcinoma. In our series of bronchiogenic tumors the ratio of incidence of benign adenoma to microscopically proved carcinoma is 1:10. If we include cases of cancer of the lung not proved microscopically the ratio is approximately 1:20. However, if we begin to talk about the results of operative treatment and narrow our discussion to resectable bronchiogenic tumors then the ratio becomes 1:4. In other words, of resectable bronchiogenic tumors we find 25 per cent are benign adenomas and 75 per cent true bronchiogenic cancers. One can readily shift the results in cancer of the lung toward the optimistic side by including these tumors. This pitfall has already been recognized. The cancer of the lung cured by bronchoscopic removal that was referred to many years ago by Jackson has been reviewed by C. L. Jackson,³ his son, and interpreted as having been a bronchial adenoma. The series of cases treated by Manges,^{4, 5} of Philadelphia, with radiation treatment, with which he got surprisingly good results, has been gone over and the good results are all interpreted as having occurred in cases with bronchial adenoma.

In passing, we might note that the young man survived the operation and should remain well without danger of recurrence or metastasis.

DR. DONALD KING It might be of interest to report our experience to date with benign adenomas. We have now observed a total of 21 cases, 11 in males and 10 in females. Of the males, 2 were over fifty years of age, 5 were in the thirties, 1 was twenty-two, and 3 were under twenty; of the females, 2 were over sixty, 4 were in the thirties, 2 were in the twenties, 1 was eighteen, and 1 was six. Of the total number, 7 are dead and 14 living. Of the dead, 1 was treated by bronchoscopy alone, 1 by bronchoscopy and radium seeds and 1 by bronchoscopies, radium and x-ray; 2 died after lobectomy, and 2 were discovered only at post-mortem examination. Of the 14 living, 5 had bronchoscopic removal of the tumor with no other treatment, 1 had radium seeds implanted, 3 had pneumonectomy, 4 had lobectomy, and in 1 the

adenoma was removed through the trachea. At the present time it seems reasonable in most cases to remove as much of the tumor as possible through the bronchoscope, but it is probable that the majority of the cases will have to have lobectomy later if the pulmonary condition is to be cured.

CASE 26172

PRESENTATION OF CASE

First Admission A sixty-six-year-old mason was admitted to the hospital complaining of an "infected corn" of about seven days' duration.

The patient was treated conservatively with moist boric applications to the foot lesion. Diabetes was discovered and he was placed on a diabetic diet with small doses of insulin. He improved steadily, the urine became sugar-free, and he was discharged to be followed in the diabetic outpatient clinic.

Final Admission (four years later) He entered the hospital because of the onset of low abdominal pain seven hours previously. About seven years before this admission the patient first noticed the onset of recurrent attacks of abdominal pain. Characteristically, without known cause or relation to food, there was a gradual onset of mild epigastric pain, which became maximal in an hour and was described as a sharp, severe, colicky distress which radiated to the left lower quadrant of the abdomen. Occasionally the pain passed from "side to side." When they occurred he was usually constipated and was subject to attacks of belching, but he passed no flatus by rectum. He was able to obtain relief from the pain by constipation and belching by either taking Epsom salts or enemas, or both. These episodes usually occurred at about bi-weekly intervals, and on rare occasions were so severe that hypodermic medication was required for the relief from pain. Three years before admission he was studied in an outside hospital where the examination, including repeated x-ray studies and a gastrointestinal series was reported as negative.

The attacks continued, and three months before entry he lost his former vigor, became weak and had to stop work. He became constipated, had frequent attacks of pain, each lasting six to seven

hours, and on a few occasions vomited "black bile," with little relief. He volunteered the information that so long as his bowels were "open" he had no discomfort. He became obstipated for several days one month before admission. Two days prior to and on the day of admission he suffered severe attacks of abdominal pain, each lasting two to four hours and leaving him with a generalized abdominal soreness. Hypodermic medication gave relief from the pain of the last attack, but six enemas attempted on the afternoon of admission were without results. He had taken no insulin prior to entry.

Physical examination revealed a sick man whose abdomen was distended, tympanitic and diffusely tender, there was slight spasm in both lower quadrants. By rectal examination there was equal tenderness bilaterally, but no masses or other abnormalities were noted. The blood pressure was 190 systolic, 70 diastolic, and the pulse was very irregular.

The temperature was 99.8°F, the pulse 94, and the respirations 20.

Examination of the blood showed a red-cell count of 3,860,000 with 65 per cent hemoglobin (Tallqvist), and a white-cell count of 5100 with 36 per cent adult polymorphonuclears, 56 per cent young polymorphonuclears and 8 per cent lymphocytes. Three days later the white-cell count was 11,100 with 96 per cent polymorphonuclears, the majority of which were young forms. The urine was negative save for a very slight trace of albumin and an olive-green sugar test. The blood nonprotein nitrogen was 55 mg per 100 cc., the chlorides equivalent to 90.5 cc. of N/10 sodium chloride, the protein 5.2 gm., the van den Bergh test normal, indirect, and the sugar 187 mg. An electrocardiogram showed auricular fibrillation, with a ventricular rate of 150, but no definite evidence of any other abnormality.

Röntgenograms of the abdomen in the supine position showed no unusual amount of gas in the bowel. A film in the upright position showed several horizontal levels with small air bubbles in the mid-abdomen. In the region of the cecum and ascending colon there was a soft-tissue mass, but it was not ascertainable whether it was the cecum filled with fecal material or a shadow of intussuscepted bowel.

The patient's temperature rose steadily, and he was obviously becoming increasingly sicker. A Miller Abbott tube was passed, but its tip failed to enter the pylorus. Urinary sugar tests after the admission specimen were negative, and there was no diacetic acid or acetone.

He was transfused, given digitalis and treated

conservatively. He quickly failed and died on the fifth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. EDWARD HAMILIN, JR. May we see the x-ray films?

DR. GEORGE W. HOLMES The gas that we see is almost wholly in the large bowel. There is a small collection here which might be in the ileum or lower small bowel. If this is small bowel, I should not call it dilated. So far as the film is concerned, we have no help whatever, except to say that there is no evidence of distended small bowel. The film taken with the patient standing shows these levels of fluid and gas. The patient had had several enemas, however, so that he may have had fluid in the large bowel, a possibility which makes this observation of no particular value. If we are going to be asked to determine the presence of abdominal fluid levels in the small bowel we should have a patient who has not had an enema just before examination.

DR. HAMILIN There is no evidence of free intraperitoneal fluid?

DR. HOLMES No, but the x-ray films do not all ways show it.

DR. HAMILIN We have a seventy-year-old man, who was apparently a mild diabetic, with a seven-year story of what sounds like intestinal obstruction. The first thing to ascertain is whether it is obstruction of the small or large bowel. The location of the pain in the mid-epigastrium is evidence of small-bowel obstruction, but because of the facts that the pain radiated to the left lower quadrant and that the attacks were always concurrent with obstipation and apparently relieved by enemas and Epsom salts—a curious way of relieving intestinal obstruction—I prefer to think that his difficulties were due to large-bowel obstruction. The attacks became worse, and he eventually entered the hospital in a very severe attack. We are not told the type of pain, the record merely states that it was abdominal pain.

The physical examination tells us nothing about whether he was cachectic but it does give us evidence of a diffusely tender abdomen, with slight spasm in the lower quadrant and tenderness by rectum.

The laboratory helps only by showing that there was obviously an attempt by the leukocytes to react to an infection of some sort. The elevated blood nonprotein nitrogen would go with either intestinal obstruction or peritonitis. Low blood chlorides usually indicate vomiting, but we have not been told that there had been vomiting in the immediate illness. I should like to know

whether the stool examination showed blood, but presumably with the enemas there was nothing on which to determine that

So we come down to the diagnosis of large-bowel obstruction of long duration, which I believe had perforated. The causes of perforation in such a large-bowel lesion may be several: an intermittent volvulus, a chronic intussusception, as was suggested by the x-ray interpretation, a diverticulitis, or possibly, if we can eliminate some of the old story, a carcinoma of the large bowel. The story is entirely consistent with diverticulitis, in fact it is almost a textbook picture, with the exception that increased flatus is usually described.

It is possible that the auricular fibrillation had led to the throwing off of an embolus and the subsequent development of mesenteric thrombosis, but if we include the entire story that does not seem likely. So with nothing more to go on, I make my first choice, diverticulitis of the cecum, with perforation and peritonitis.

DR TRACY B MALLORY: Would anyone care to offer another diagnosis? Dr Hamlin's diagnosis agreed with the discharge diagnosis on the ward.

DR WYMAN RICHARDSON: I suggest a diagnosis of large-bowel obstruction, probably due to carcinoma of the large bowel.

CLINICAL DIAGNOSES

Generalized peritonitis
Diverticulitis, acute
Arteriosclerosis, generalized
Diabetes, mild

DR HAMLIN'S DIAGNOSES

Diverticulitis, acute, with perforation
Generalized peritonitis

ANATOMICAL DIAGNOSES

Obstruction of ileum from adhesive band (? congenital)
Perforation of ileum
General peritonitis
Meckel's diverticulum
Hypertrophy of prostate, benign, lateral lobe, slight
Trabeculation of bladder, slight
Nephritis, chronic vascular, slight
Arteriosclerosis, coronary arteries and aorta, slight
Pulmonary atelectasis

PATHOLOGICAL DISCUSSION

DR MALLORY: This was a very blind case, and in retrospect the only possible lead was the original localization of the pain, the lesion was in the small bowel and not the large. It was of rather unusual character. He obviously had had chronic obstruction of the lower ileum for many years due to a very dense fibrous adhesive band, which was not accounted for by any previous operation. So the question arises as to whether this band was congenital in origin. The other finding was an entirely unsuspected Meckel's diverticulum, which lay 30 cm above the adhesive band and had nothing to do with it. However, just above the adhesion was a small perforation of the ileum, about 1 cm in diameter, from which general peritonitis had resulted. It was, apparently, a spontaneous rupture immediately behind the point of obstruction. There was no neoplasm.

A PHYSICIAN: You might well have expected some free gas in the abdomen.

DR ARTHUR W ALLEN: The films were probably taken before perforation occurred.

PROGRESS IN CANCER CONTROL

SINCE April has been dedicated as Cancer Month, it is appropriate that the Division of Adult Hygiene of the Massachusetts Department of Public Health,* which is charged with the cancer control work in this state, should report on its activities and accomplishments during 1939.

Again, Massachusetts has the proud distinction of being the only state in the Union, indeed the only place in the world, which had a falling cancer death rate in women. There was also a slight drop in the rate for men.

The attendance of cancer patients at the cancer clinics has increased from an average of 758 per year prior to 1935 to 1676 in 1939. Of the latter patients, 22.4 per cent went to their physicians within a month of the first symptoms of the disease. This

is an all-time record for early diagnosis of cases of cancer.

The interest of physicians in the cancer clinics is shown by the facts that 85 per cent of the patients coming to the clinics were referred by physicians, that the clinics are voluntarily staffed by physicians in the local communities and that the annual attendance of physicians at consultation and teaching clinics has increased from an average of 229 for the first years of the program to 1364 in 1939.

An increase has also been noted in the utilization of the Tumor Diagnosis Service, maintained jointly by the Massachusetts Department of Public Health and the Harvard Cancer Committee for the use of those physicians without adequate laboratory facilities for the histological diagnosis of cancer. The average number of specimens received for diagnosis from 1927 to 1935 was 2813 annually. In 1939, 3620 were received, and the number of surgeons using the Tumor Diagnosis Service increased from an average of 421 to 738.

The Massachusetts Medical Society may well congratulate itself on the work that it has done in furthering the diagnosis and treatment of cancer. But it must not regard its responsibility as in any way lessened, but rather heightened, by the fact that apparently this particular enemy of mankind is in grudging retreat.

ARMY EXPERIENCE FOR PHYSICIANS

AN announcement, published elsewhere in this issue of the *Journal*, indicates the intention of the War Department to offer one year of active duty with the United States Army to civilian physicians under thirty five years of age who will accept appointment in the Medical Corps Reserve in order to permit them to be placed on such duty.

This announcement is, in effect, an invitation to the medical profession to contribute its share in time of peace toward the organization of national defense. Congress has provided for augmentation of the strength of the Army, both in the regular establishment and in the National Guard. Peacetime maneuvers on an unprecedented scale are authorized and planned for the spring and

Cancer Bulletin No. 81 Massachusetts Department of Public Health, Division of Adult Hygiene, April, 1940.

summer of this year Reserve officers are being called to active duty for specified periods of time in order to expedite augmentation in an orderly fashion and to provide commissioned personnel for the maneuvers to be held

The compelling logic underlying these plans, in the unsettled state of the world at present, can scarcely be questioned. The proposal to offer reserve commissions to young qualified physicians is intelligent and timely, since the Army not only may attract some of them into the regular service but also will train the majority to perfect themselves for the possible, if fervently undesired, day when wartime mobilization takes the place of peacetime maneuvers.

The announcement should offer a distinct appeal to many recent graduates in medicine who have either finished or are about to finish their training as interns. The year of service, if accepted, is essentially a postgraduate internship in military medicine with rates of pay and allowances set at assured and attractive levels. An unequalled opportunity is presented to learn the duties of the physician as an officer, duties which become more specialized in the military sense as new tactics and technics are adopted by the combat branches. He who secures active service for a year under the conditions offered can be well satisfied that he is not only discharging a fundamental civic duty but is also preparing himself to play an essential part in the event of disaster afflicting this nation as it has already afflicted so many other peaceful ones.

MEDICAL EPONYM

BOWMAN'S CAPSULE

William Bowman (1816-1892), assistant surgeon to the King's College Hospital and demonstrator of anatomy in King's College, London, read before the Royal Society on February 17, 1842, a paper "On the Structure and Use of the Malpighian Bodies of the Kidney, with Observations on the Circulation through that Gland." This was printed in the *Philosophical Transactions of the Royal Society of London* (132: 57-80, 1842).

The Malpighian bodies I saw to be a rounded mass of minute vessels invested by a cyst or capsule* of precisely similar appearance to the basement mem-

brane of the tubes. Seeing these similar tissues in such close proximity, it was not easy to resist the conviction that the capsule was the basement membrane of the tubes expanded over the vessels. Having, during last summer, been made acquainted, through the kindness of Dr. Milne Edwards, with a new method of injection employed with great success by M. Doyère of Paris,** I injected some kidneys through the artery, by this method, in order to notice the nature of the vascular ramifications in the Malpighian bodies. I not only found what I sought, but the clearest evidence that the capsule which invests them is, in truth, the basement membrane of the uriniferous tube expanded over the tuft of vessels.

*First particularly pointed out by Muller who conceives it to be perfectly closed except at one point where perforated by the vessels.

**This consists of two fluids which mingle in the small vessels, and cause a precipitation there. The best fluids are saturated solutions of bichromate of potash and of acetate of lead. They are injected in succession through the same vessel whence the method is termed that by double injection. Krause published an account of it two years ago but M. Doyère appears to have arrived at it after a laborious trial of numerous solutions. Both deserve the thanks of anatomists for so valuable an addition to the means of investigation.

OBITUARY

LEROI GODDARD CRANDON

1873-1939

On December 27, 1939, Doctor LeROI G. Crandon died after a long and slowly progressive, but happily painless, illness. To very many of us who called him "friend," the occasion of his death would seem to call for some comment, however brief, in the columns of the *Journal*. We are not sure that he would have desired any such comment.

His educational equipment was of the best, both by inheritance and acquisition. His father, a strikingly handsome, lovable and courteous gentleman, was originally a minister of the Unitarian Church but later became associated with the Society for Ethical Culture. He was an ardent and discriminating collector of books, a trait strongly inherited by his son. His mother and sisters also supplied a sturdy New England background of intellectuality and clear thinking. Doctor Crandon received his A.B. *cum laude* from Harvard University in 1894 and his M.D. *cum laude* in 1898. Many years later (1909) and while carrying on a very large and insistent practice, he worked for and received his A.M. in philosophy from Harvard University. How he ever found time to do the hard work and intensive reading required for this particular degree, all the while engaging in a practice that carried on night and day, almost beggars understanding. His endurance seemed endless. Working tirelessly throughout the day

and evening (and often into the night) on public and private hospital patients, he not infrequently studied until two or three o'clock in the morning. It is doubtful if he ever averaged more than five or six hours sleep during this period. And yet through it all he maintained a serenity of manner and an unusual quietness of speech, not always properly appraised by some of his colleagues.

Receiving an appointment in surgery at the Boston City Hospital in 1898, he made a brilliant record as a house officer, and in 1903 became a member of the Visiting Surgical Staff, holding that position until 1919, when he resigned. As a surgeon he was conservative, sure of his technique, meticulous as to details, never spectacular and possessed of excellent surgical judgment. Fortunately were those house officers who had their training under him, and doubly fortunate the patients who came under his direct professional care. He was a master of postoperative care, and his book, *Surgical Aftercare* embodied all the principles he practiced and taught, the book went through two editions, was adopted by the United States Army and went through several translations into foreign languages. He taught surgery for many years at the Harvard Medical School, both clinical and laboratory, the latter consisted of operative surgery on the cadaver and was conducted in conjunction with the late Dr. George H. Monks. His surgical papers were many and valuable, especially those dealing with diseases of the prostate, appendicitis, fractures of the base of the skull, and difficulties with the feet due to improper shoes. His style was direct and forceful with well-chosen words and phrases. His expressed ideal in these respects was the late Dr. David W. Cheever, whose scholarly lectures on surgery—later printed in book form but unfortunately not now readily available—were his model.

During the World War he served in the Navy at New London, Connecticut, organizing United States Naval Hospital, No. 9, a thousand-bed plant. His excellent service was recognized, and he shortly was promoted to the rank of lieutenant commander. He was later given the rank of commander.

Of avocations Doctor Crandon had few. He was a great lover of books, and his collection on Arctic exploration was outstanding in character and number of volumes. Over a long period, yachting was an engrossing pastime with him. An able navigator, he possessed in the course of years two fine schooners, the *Nokomis* and the *Black*

Hawk both of which he himself sailed. For a time he was commodore of the Boston Yacht Club.

No sketch of the life of Doctor Crandon would be complete without some reference to what became to him in his later years a matter of most intense devotion. In 1923 he became absorbingly concerned with psychic research. This interest was stimulated and made possible by the mediumship of his wife, Mina Stinson Crandon ("Margery"), and lasted until his failing health called a halt. He became an active member of American and British societies for psychical research, his interest being, as he himself said, purely objective and scientific. He made several trips to England for discussion of scientific matters bearing on psychic phenomena with Sir Conan Doyle and Sir Oliver Lodge, and in turn was visited very many times in his home on Lime Street by scientific investigators from this country and abroad. As one of Doctor Crandon's closest friends says of him, "Brilliant as was his surgical career, it is probable that he will be remembered more especially for his connection with psychic research." To the end, he was the scientific observer of these psychic phenomena. Mediumship has always been a controversial and bloody battleground, and that of "Margery" was no exception. Doctor Crandon believed absolutely and unwaveringly in the integrity of the mediumship of his wife. So believing, he fought valiantly, asking and giving no quarter, and regardless of the number or the character or the fame of the opposition. As is well known, they left nothing undone to discredit him. Knowing the man as some of us did, one can be certain that he would have been the first to demolish the whole structure and admit its fallacies if he had believed for one moment that the observed psychical phenomena were unsound or explainable by purely natural methods.

To a host of patients, Doctor Crandon, because of his unremitting devotion, kindness and skill, was the ideal and beloved physician. To a very great number of doctors to whom he was always an unfailing friend, able counsellor and skillful surgeon, he was a never failing help, and their devotion and loyalty to him were as great as the regard of his patients. A remarkable tribute to the real affection and respect which so many people of all walks of life held for him was shown in the outpouring of the friends who attended the funeral service. All felt a deep and heartfelt grief at the loss of a friend.

MASSACHUSETTS MEDICAL SOCIETY

SECTION OF OBSTETRICS
AND GYNECOLOGY

RAYMOND S. TITUS, M.D., *Secretary*
330 Dartmouth Street
Boston

Beginning on September 28, 1939, and running through April 18, 1940, cases dealing with the treatment of uterine sepsis were presented in the *Journal*. An attempt was made to show the change from unintelligent to intelligent treatment—from invasion of the uterus and symptomatic treatment to that based on non-interference with the uterus and a knowledge of the specific infectious agent. The policy of letting the uterus alone evolved from the observation of the dire results that frequently followed its invasion. It is surprising that it took the profession so long to conclude that puerperal infections should be attacked from the etiologic point of view, but this was undoubtedly stimulated by the recent successful treatment with chemicals of other diseases of known bacterial etiology. Today the treatment of such infections is intelligent. The uterus is looked on only as the portal of entry of the infection, and is never itself invaded except for hemorrhage. The disease is attacked, as are nearly all other infections, by attempts, with stained smears and cultures, to determine the bacterial invader, and the method of treatment depends on this specific knowledge. In this respect the treatment of puerperal sepsis has at last been placed on a solid foundation, and the results are very gratifying. The few cases of cesarean section that were reported illustrate that subsequent sepsis without peritonitis should be treated in the same way as sepsis following pelvic delivery.

In the subsequent issues of the *Journal* a series of cases of pyelitis during pregnancy will be presented. The first ones will be those treated twenty-five years ago, when treatment was entirely symptomatic. These will be followed by cases in which kidney lavage played an important therapeutic role. Lastly will be the recent cases in which lavage and chemotherapy have been used with excellent results.

THE MASSACHUSETTS CANCER PROGRAM*

The Massachusetts Cancer Program has just completed its thirteenth year of operation. The results of this long-continued attack on cancer are being realized. During the past year the outstanding accomplishments were a continuation of the shorter period of delay between first

recognizable symptoms and visit to physician first noted in 1936, a larger percentage of individuals going to their physicians in the first month of the disease, a far greater use of the Tumor Diagnosis Service, more individuals coming to the clinics than ever before, sixty three teaching clinics attended by 1364 physicians, an extension of the Co-operative Cancer Control Committees, and the opening of two new cancer clinics.

Question During the past few weeks I have heard a large number of physicians ask if the fall in the cancer death rate among women is continuing. This seems to be the most important question in the minds of those interested in cancer. Will you discuss this?

Dr. Lombard The 1939 adjusted cancer death rate for women again showed a decline over the previous years. This decline from the all time high in 1925 of 1300 per 100,000 population is now approximately 4 per cent. This may not seem large, but it represents a saving of several hundred lives, and if the decline continues in the years to come, many more lives will be saved.

Question The question of delay is another of great importance. In the cancer clinic population there are three types of delay—that before the visit to the first physician, that between this period and attendance at a clinic and that between attendance at the clinic and treatment. In the ordinary hospital population there are only two types of delay—that before the visit to the first physician and that between the visit to a physician and the institution of treatment. The summation of all delays depicts the time wasted between first symptoms and treatment. Will you differentiate these delays and discuss their significance?

Dr. Lombard The interval between first symptoms and the visit to first physician represents a delay on the part of the public. In the early part of the program this delay was nearly seven months. In the last few years it has been decreasing, and in 1939 it was only five months. This, of course, is too long, but it shows that the educational efforts being expended by the Massachusetts Department of Public Health and co-operated in by some 15,000 organizations in the State are having results. The second delay, that between the visit to a physician and attendance at a clinic, was only about one third as long last year as in the early days of the clinic. The third delay, that between attendance at a clinic and treatment, is very short due to the excellent work of the social service departments. While the total delay in Massachusetts clinics averages some nine months, it is much shorter than that reported from other states, and it is also shorter than that reported from Massachusetts hospitals. Apparently the reason for this is the shortening of the interval of delay between visiting a physician and treatment brought about by social service workers in the clinic population.

Question In what way does social service work play its part in the clinic set up?

Dr. Lombard At the first visit of the patient to a cancer clinic, information is obtained by the social service worker regarding the symptoms and their duration, the motivating cause for coming to the clinic, identifying data, age, sex, whether other doctors had been consulted, the interval since onset of symptoms that had elapsed prior to first consultation with a physician and the interval between first consultation with a physician and consultation at the clinic, and the reasons for delay in seeking diagnosis. One of the physicians in charge of the clinic dictates the medical findings and the recommendations. The patient is returned to his physician and treatment is determined by this physician, and effected in some cases

* Green Lights to Health—broadcast given by Dr. Herbert L. Lombard on Wednesday March 27 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

nth and in some cases without the assistance of the social service worker in making arrangements. The worker allows each cancer patient, obtains hospital transcripts of operations and other therapy, and keeps in touch with the patient throughout life. If the patient moves, the record is continued by the worker in the section of the new residence. If the patient leaves the State, attempts are made to contact him through existing agencies. The majority of lost patients are those who have left the State and with whom it is impossible to establish a local contact.

Question What happens to these records?

Dr Lombard All these records are verified, coded and indexed and tabulated by experienced workers under the supervision of an experienced biometrician.

Question Did more people come to the cancer clinics last year than formerly?

Dr Lombard Over 5000 individuals attended the cancer clinics in 1939. This was the largest number that has ever been seen at these clinics. However the cancer patients at these clinics represent only about 10 per cent of the total number of cancer patients of the entire State. It is true today as in the early part of the program that the majority of individuals with cancer go to their family physicians. With this in mind the department is endeavoring to help these physicians as much as possible. This is being done by furnishing them with the latest literature on cancer and conducting teaching clinics for their benefit. This spring through funds made available from the Federal Government and the Women's Field Army a monograph on cancer is to be furnished every physician and all libraries in the State. This should be of inestimable help. The physicians are also helped by the Tumor Diagnosis Service, to which every physician in the State may send tissue specimens, suspected for malignancy for diagnosis.

Question Has the use of this service been increasing?

Dr Lombard The number of specimens received last year far exceeded that of any preceding year. A part of his increase is believed to be due to the extension of the Co-operative Cancer Control Committee.

Question I understand the function of these committees is to invite a local physician to speak to them on cancer at least once a year. I also understand that all the organizations of a given community belong to this organization. How near completion is the total organization?

Dr Lombard We have contacted over 80 per cent of the organizations in the State and invited them to join in this movement. It is expected within the next year that the remaining organizations will be enrolled in the Co-operative Cancer Control Committee. When you consider nearly 20,000 organizations eventually functioning and asking their physicians to address them each year on the subject, the educational value of this program may be seen to be enormous.

Question What is the relation between the clinics and the educational program?

Dr Lombard There is no direct connection between these two organizations. The function of one is limited to education of the public that of the other to furnish consultative service for the diagnosis of cancer. It is perfectly true that the attendance at the clinics increases proportionately with the amount of education in the community and for a rounded cancer program both functions are necessary. Administratively they are entirely separate, from the standpoint of cancer control they are closely united.

Question Do you think there is any relation between the Tumor Diagnosis Service and education?

Dr Lombard There is no administrative connection between these two services but the volume of specimens sent to the Diagnosis Service is greater after a community has been organized into the Co-operative Cancer Control Committee than formerly. It is probable that the cancer consciousness which increases in the community with the functioning of the Co-operative Cancer Control Committee stimulates interest and as a consequence, a larger number of tumors suspected of being cancerous are sent to the service.

Question What is the connection between the clinics and the hospitals?

Dr Lombard Every clinic is located in a hospital. The hospital furnishes the room for the clinic, the equipment and nursing service. Patients, however are not referred directly from the clinic to the hospital unless their attending physician so desires. All patients are returned to their physician, and he determines the place for treatment. Some patients return to the hospital at which the clinic was located some go to one of the two state cancer hospitals while some go to other hospitals.

Question Is the attendance at clinics weighted by the lower economic group or does it represent a cross section of the population?

Dr Lombard The clinics are open to anyone in the State regardless of his financial status. It is true that a large number of the population that attend the clinics are from the low income group. It is also true that a few people with large incomes go to the clinics, but the cross section of the clinic population is of a lower financial rating than a cross section of the total population of the State.

Question Does the clinic population present particular types of cancer in the ratio of their total occurrence?

Dr Lombard Although the clinic population measures about 10 per cent of the cancer load it is not evenly distributed by types of cancer. It is heavily weighted with cancers of the mouth, breast, uterus and skin, and contains less than 10 per cent of digestive-tract cancers.

Question What is the interrelation between the medical profession, the general public and the Department of Public Health in this effort to control cancer?

Dr Lombard The interrelation lies primarily in the oneness of purpose—the desire of each, in its own sphere, to improve the cancer situation. The essence of the success of the educational methods of the Massachusetts Cancer Program lies in its inherent sharing of known facts about cancer by a generous and informed profession with a co-operative and receptive public. Fears are not stressed they are rationalized. Symptoms are not presented as the basis of exact knowledge they are merely alluded to in the discussion of the large problem. The physician with his increasing interest in the progressive steps of the knowledge of the disease, presents the subject simply and intelligibly. The public, responding as an individual would respond to a real discussion of an absorbingly interesting subject, rises to the mental challenge of this approach. As a result, all classes, groups, races and professions are united in this basic co-operative and successful program which disseminates exact knowledge concerning cancer. This engenders a realization of the need for prompt action. Exact knowledge and prompt action effect control.

DEATHS

CALLANAN—**FRANCIS J. CALLANAN, M.D.**, of Boston, died April 21. He was in his forty-fifth year.

Born in Boston, he attended Harvard University and received his degree from Harvard Medical School in 1918. He served his internship at the Massachusetts General Hospital. Dr. Callanan was a trustee of the Boston State Hospital, secretary of staff of the Massachusetts Women's Hospital and a member of the board of directors of the Household Nursing Association.

He was a member of the Massachusetts Medical Society, the American Medical Association and the American College of Surgeons.

His widow, a sister and a brother survive him.

RICE—**WALTER H. RICE, M.D.**, of Boston, died April 19. He was in his sixty-ninth year.

Born in Fitchburg, he graduated from Tufts College Medical School in 1896 and from Harvard Medical School in 1899. He also studied in Rome and Munich and had served at Charcot's clinic in Paris.

He was a fellow of the Massachusetts Medical Society and the American Medical Association.

A son, two sisters and a niece survive him.

WALCOTT—**HENRY J. WALCOTT, M.D.**, of Concord, died April 17. He was in his sixty-eighth year.

Born in Concord he graduated from Columbia Institute in New York and received his degree from Jefferson Medical College of Philadelphia in 1896. Dr. Walcott had been medical examiner for the Thirteenth Middlesex District for the past twenty-eight years and surgeon at the state reformatory at Concord for thirty years. He was one of the founders of the Emerson Hospital, Concord, and at the time of his death was the senior member of its staff.

He was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow, a son, a daughter and three grandchildren survive him.

YOUNG—**EDWARD W. YOUNG, M.D.**, of New Bedford, died April 16. He was in his fifty-fourth year.

Born in Taunton he received his degree from Tufts College Medical School in 1913. After serving his internship at St. Luke's Hospital, New Bedford, he set up his practice there.

Dr. Young was a member of the Massachusetts Medical Society, the American Medical Association and the New Bedford Medical Society. He was also on the staff of St. Luke's Hospital.

His widow, a daughter, a sister, three brothers and a nephew survive him.

MISCELLANY

ARMY EXPERIENCE FOR PHYSICIANS

An interesting medical corollary to the augmentation of the United States Army during 1940 and 1941 and to the planned large scale Army maneuvers during the spring and summer of 1940 is the broad medicomilitary experience which a great number of civilian physicians will receive. Medical reserve officers are being used to augment the entire Army Medical Service, which includes everything from small unit installations to large station hospitals, general hospitals and hospitals designed primarily for the treatment of specific types of cases.

Physicians under thirty-five years of age who are desirous of obtaining extended active duty with the Army but who do not hold reserve commissions are being offered appointments in the Medical Corps Reserve in the grade of first lieutenant, in order to permit them to be placed on such duty. Captains and lieutenants are at present being offered excellent assignments throughout continental United States, and it is hoped that authority will be granted to permit some officers to go to Hawaii and Panama. In addition to having a new and very busy experience in the practice of medicine, the average officer finds the pay and allowances attractive. The pay and allowances for a married first lieutenant amount to approximately \$263 a month, for a single first lieutenant to approximately \$225 a month, for a married captain to approximately \$316 a month, and for a single captain to approximately \$278 a month. In most cases the above pay and allowances would apply inasmuch as government quarters are not usually available for officers on extended active duty. In the few cases where government quarters are available, the amounts would be \$40, \$60, \$60 and \$80 less per month respectively. In addition, the officer is reimbursed for mileage traveled from his home to his station, and on completion of his tour of duty is reimbursed similarly for the travel to his home.

Application for one year of active duty, or for appointment in the Medical Corps Reserve with a view to obtaining one year of active duty with the Army, should be requested at once by a letter addressed to the commanding general of the corps area wherein the physician permanently resides. In addition, the application should contain concise information regarding permanent address, temporary address, number of dependents, earliest date available for active duty, and that internship has been (or will be) completed, and it should be accompanied by a report of physical examination recorded on the Army Form WD AGO 63, which may be obtained from any Army station. From the group of reserve officers placed on extended active duty since August, 1939, over 2 per cent of those within the age requirements of thirty-two years or less for commission in the Army Medical Corps found military service sufficiently to their liking to cause them to take entrance examinations for the United States Army. Inquiries from those residing in the First Corps Area (Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut) should be addressed Army Base, Boston 9, Massachusetts.

CITY AND RURAL HEALTH CONSERVATION CONTESTS

Winners in the 1939 City and Rural Health Conservation Contests were recently announced by the Chamber of Commerce of the United States. These contests are conducted annually by the organization in co-operation with the American Public Health Association for the purpose of furthering adequate health protection and health promotion services throughout the United States. The competent manner in which a community is meeting its health problems is the basis on which the awards are made. This does not necessarily mean that awards are made to the healthiest communities. A group of public health experts from all parts of the country carefully appraise each participating city and county. Each community is graded on what measures it takes to provide and safeguard its water supply, to furnish adequate and safe sewerage disposal, to reduce infant and maternal deaths, to combat tuberculosis and syphilis, to protect its citizens against other communicable diseases, to ensure

healthy children to protect and safeguard its milk and other foods, to promote effective co-operation with its physicians and dentists in furnishing necessary services to all those who need them and to enlarge and improve its lay-understanding of ways and means of preventing sickness and death and of maintaining good health.

In the City Health Contest the winner in Group I (cities of over 500,000 population) is Milwaukee, Wisconsin, with an award of merit to Baltimore, Maryland. In Group II (cities of 250,000 to 500,000 population) Memphis Tennessee, is the winner, with awards of merit to Louisville, Kentucky Newark, New Jersey Dallas, Texas, and Toledo, Ohio.

In Group III (cities of 100,000 to 250,000 population) the winners are tied,—New Haven and Hartford, Connecticut,—with awards of merit to Grand Rapids Michigan, Yonkers, New York, Reading, Pennsylvania, Springfield, Massachusetts, and Erie, Pennsylvania. The winner in Group IV (cities of 50,000 to 100,000 population) is Newton, Massachusetts, with awards of merit to Evanston, Illinois, Schenectady, New York, Pasadena, California Madison, Wisconsin, East Orange, New Jersey Racine, Wisconsin, and Sacramento California.

In Group V (cities of from 20,000 to 50,000 population) the winners are tied,—Greenwich Connecticut, and Plainfield, New Jersey with awards of merit to Hackensack, New Jersey Winona Minnesota, Brookline, Massachusetts, Stamford, Connecticut, and Orange, New Jersey. The winner in Group VI (cities of less than 20,000 population) is Englewood, New Jersey with awards of merit to Asbury Park, New Jersey Hibbing Minnesota, and Virginia Minnesota.

In the Northeastern Division of the Rural Health Contest the winner is Alger-Schoolcraft Health Unit, Michigan. Awards of merit go to District No. 7, Gladwin Michigan Chippewa County Michigan, District No. 2, West Branch Michigan Mecosta-Oscoda Health Unit, Michigan, Wayne County Ohio, Saginaw County Michigan, Barnstable County Massachusetts, Lorain County, Ohio, and Berkshire District, Massachusetts.

NOTES

The appointment of Dr. Kurt Goldstein as clinical professor of neurology at Tufts College Medical School made possible by a five year grant for teaching and research in neurology from the Rockefeller Foundation was recently announced by President Leonard Carmichael. Dr. Goldstein will begin his appointment on June 1. He was William James Lecturer at Harvard last year and since 1936 has been on the medical faculty at Columbia University and chief of the Neurological Laboratories at Montefiore Hospital in New York City. Dr. Goldstein will be attached to the Neurological Clinic of the Boston Dispensary.

Five awards for study at the Harvard Medical School during the next academic year were recently announced as follows: George Chase Christian Memorial Scholarship to John E. Skogland, M.D., University of Minnesota 37 of Keewauqua, Minnesota, at present clinical instructor Division of Nervous and Mental Diseases, University of Minnesota. Daniel A. Buckley scholarships to William J. Baker 234, of Cambridge, and Chester J. Dziengielewski 4C, of Cambridge. Frederick E. Parlin Scholarship to Irving M. London 1M of Malden Stoughton Scholarship to George S. Kurland 4C, of Dorchester.

REPORTS OF MEETINGS

WILLIAM HARVEY SOCIETY

At a regular meeting of the William Harvey Society of Tufts College Medical School held at the Beth Israel Hospital on January 12 Dr. Stanhope Bayne-Jones, dean of the Yale University School of Medicine, spoke on "The Relation of Viruses to Cancer." In opening his address he made some general remarks about the properties of viruses, such as their size and the question of whether or not they may all be considered as living organisms. The isolation of the virus of tobacco mosaic disease and those of other types, he said, is not considered by geneticists and crystallographers incompatible with living matter. The manner of their reproduction was considered as possibly autocatalytic, a sort of spontaneous generation under a new name. In support of such a theory the experiments of Northrop Stanley and others were cited. In general viruses may be necrotizing and destructive, such as that of vaccinia or proliferative, such as those of contagious epithelioma and chicken sarcoma.

Dr. Bayne-Jones then discussed some examples of tumor formation initiated by a virus. First was chicken sarcoma, which has been produced repeatedly by cell free filtrates of the tumor. It was suggested that the virus might be the determining factor in the type of tumor resulting. A less well known example of a virus tumor is adenocarcinoma of the kidney in the frog. Then was cited fowl leukemia, which appears to have had its virus etiology proved despite the evidence that a leukemic cell is necessary for the transmission of leukemia in mice. And since this latter disease is not transmissible after ultra filtration careful scrutiny was advised for all investigations where the presence of cells, as well as of the filterable virus, is possible or questionable.

An outstanding characteristic of these tumors is that one may recover potent cell-free filtrates from the tissue, and in amounts proportional to the growth of the tumor. The same is not true in similar neoplasms in mammals, however. Thus, in the Shope rabbit epithelioma the virus disappears from the papillomatous growth in many cases, particularly in domesticated animals. And yet these tumors may progress from benign to malignant stages in the absence of demonstrable virus. It has been assumed by Rous and the other proponents of a virus etiology for tumors that this absence of an ultrafilterable factor may be explained by its neutralization by the tissue fluids of large carcinomas.

One of the most convincing experiments in support of the virus theory was the production by Rous of carcinomas in inadequately tared rabbits by the added influence of the Shope virus. It had been predetermined that the exposure of a susceptible surface to a carcinogenic tar required a minimal amount of rubbing in order to ensure a high incidence of epitheliomas. It was in a group of rabbits proved to be insufficiently treated by such standards that Rous was able to raise markedly the incidence of carcinomas by the supplementary use of the Shope virus.

Dr. Bayne-Jones stated that it was an accepted fact that tumors could be produced by viruses in frogs and fowl and that a virus was demonstrable in these tumors. On the other hand, one has not been able to extract a filterable virus of tumor-producing potentialities from mammalian malignant tumors.

Dr. Bayne-Jones concluded his discussion in an attempt to stimulate his audience to seek the ultimate mechanism of malignant change whereby cells become "not lawless but assume a law of their own." Any reproducing cell

was represented as being potentially malignant, and any increased potentiality, once present, was considered permanent. The many remote causes of cancer cited by the speaker—those responsible for the "causogenesis" of Murphy—included the hydrocarbons, the azo dyes and simple zinc chloride. The opponents of the virus theory place viruses in this category, while the proponents would like to think of them as intimate causes

CUTTER LECTURE

The first 1940 Cutter Lecture on Preventive Medicine was given at the Harvard Medical School on January 15, with Dr John E Gordon introducing the speaker, Dr Ludvig Hektoen, executive director of the National Advisory Cancer Council and emeritus professor of pathology at the University of Chicago. His subject was "Cancer Control, with Special Reference to Public-Health Aspects." The speaker inaugurated his discussion by reminding his audience that the prime purpose of any cancer program should be to promote the prevention of cancer and to do the best that can be done at the time for the cancer patient no matter what his means or the stage of his cancer. Dr Hektoen attempted only to explain the features of the control aspects of the program, leaving the research problem for a subsequent lecturer.

Allusion was made to the basic importance of education in any attempt to bring about the early diagnosis and prompt treatment of a condition where the first step depends on the patient. Special tribute was paid to the capable work in this phase by the American Society for the Control of Cancer. A second fundamental necessity, where there may exist lack of financial means as well as of knowledge, is for governmental subsidy of some nature. The prototype of such a system is that existing in Massachusetts, where there are two state cancer hospitals, a free, tumor diagnostic service and twenty-two state-aided clinics strategically located to care for the needs of the indigent and the medically indigent patient. This example has been more recently followed by an increasing number of states, subsequent to the demonstration by Massachusetts of a definite reduction in the adjusted cancer death rate for women and a similar suggestive trend for men.

One of the pioneer states in the field of cancer investigation was New York, which in 1898 established a laboratory for research, and in 1910 made available a free diagnostic clinic. Dr Hektoen read part of a recent report from the New York state commission, in which it was concluded that diagnostic facilities were lacking in hospitals of less than 100 beds, that there was a poor geographic distribution of x-ray facilities and tumor clinics so that there was need of 25 additional units in each instance, and that the follow-up of cases and terminal care were not adequate. The commission suggested that the guiding principle should be a tendency to decentralization and to more efficient use of already existing institutional facilities. Further recommendations favored a reorganization of the public-health system to include a cancer-control program, the compulsory reporting of cancer cases, an improved follow up system for state-aided clinics, and a statistical and epidemiological study of the problem. It was concluded from their study that a proper use of the available knowledge concerning cancer could produce a lower death rate from this condition.

The vast proportions which the cancer problem is rapidly assuming were suggested by an analysis of a survey of the Veterans' Administration, which has 4,000,000 men under its care. Between 1938-42, when the average age of these men is forty five to forty-nine years, 20,000 deaths

might be expected from cancer, while twenty years later this number, under present conditions, would be trebled. This unit has already outlined a plan to combat the scourge by education, early diagnosis and prompt treatment. Six centers have already been set up, the largest with accommodations for 400 men.

Dr Hektoen went on to discuss the attempt of the American College of Surgeons to elevate the standards of cancer centers by listing approved clinics of more than 100 beds. There are now 307 such clinics, of which 42 are diagnostic only. A steady increase in the number has indicated that their value has been accepted.

In regard to the role of the local physician, the speaker stressed that he is often the first man whose advice is sought for evaluation of a patient's suspicions and for advice as to a proper clinic to attend for diagnosis and treatment. Although there is some limitation at present in diagnosis and treatment, there is none in prevention, Dr Hektoen stated. Among preventable neoplasms cited were those following exposure to tar, dyes and roentgen rays and those developing on pre-existing areas of chronic inflammation, particularly in the gastrointestinal tract, uterus and skin. A more recently recognized condition which should probably be included is the premalignant degeneration of the oropharyngeal mucosa found in the Plummer-Vinson syndrome subsequent to long-continued malnutrition.

Finally, Dr Hektoen discussed the role of the Federal Government in the cancer problem. The federal cancer program of May 5, 1937, set up a National Cancer Institute to study the problem in all its ramifications, to correlate various forces, to obtain radium, to train competent specialists, to provide and administer fellowships, and to arrange for national and international consultations whenever necessary for the elucidation of problems. There is also a National Advisory Cancer Council of six members, with the surgeon general as *ex-officio* chairman, which makes recommendations for research, spreads educational propaganda and reviews applications of institutions and individuals seeking grants. Appropriations voted for the work amounted to \$400,000 in each of the years 1937-8 and 1938-9, with \$570,000 being available for the present fiscal year. The sum of \$150,000 was used for the erection of a building to house the National Cancer Institute, where research is being conducted into the types of carcinogenic substances, their modes of action, the biology and biochemistry of cancer cells, and the evaluation of new and revived types of therapeutic agents, with particular reference to the efficacy of various roentgen-ray voltages and isotopes of radio-active substances. The speaker also mentioned the advantages resulting from the collaboration of federal agencies with other institutions and local public-health boards.

In conclusion, Dr Hektoen stated that lack of intelligent organization and co-operation was largely responsible for the inadequate use of available knowledge and facilities, and consequently was an obstacle in attaining a reduced cancer death rate.

HARVARD MEDICAL SOCIETY

A regular meeting of the Harvard Medical Society at the Peter Bent Brigham Hospital on January 23 was presided over by Dr Robert Zollinger.

The first case, presented by the medical service, was that of a sixty-seven-year-old Pullman porter, who entered the hospital because of pallor of one week's duration and exertional dyspnea for three months. Forty years previously the patient had had a primary syphilitic lesion, and his wife was known to have had a typical syphilitic preg-

ancy cycle. Two years before entry an attack of mild rhinitis had responded to bedrest, and six months before here had been an episode of severe migratory arthritis successfully treated by salicylates and bedrest. Exertional typica, first noted three months prior to entry had become more marked after two months, and the patient as digitalized by his local physician. Paroxysmal dyspnea while at complete rest was a recent development, as was also difficulty in dexterous manual maneuvers. Physical examination revealed a Negro with marked pallor and gray hair which had been present since the age of twenty-five. Dyspnea was easily brought about. The pupils reacted normally but the fundi showed old and recent hemorrhages and "cotton-wool" exudate. The heart was enlarged, and there was a medium grade apical systolic murmur. The knee jerks were symmetrically diminished, the ankle jerks absent, and vibratory sensations normal. Laboratory data revealed an erythrocyte count of 30,000, a leukocyte count of 5900, a hemoglobin of 28 per cent and a stained blood smear exhibiting extreme macrocytosis with marked polychromatophilia and numerous sickle-shaped erythrocytes. The platelet count was 80,000, and cell volume studies showed a hematocrit of 12.5 per cent and a mean corpuscular volume and mean corpuscular hemoglobin concentration about twice the normal values of 85 to 100 cubic microns and 26 to 32 micrograms respectively. The Hinton test was positive. Treatment consisted of transfusion with subsequent increase of the erythrocytes to 1,000,000. The use of intramuscular liver extract caused an increase in the red-blood-cell count of about 1,000,000 per day and elicited a response of leukocytes that reached a peak of 29 per cent in four days.

Dr. Soma Weiss, in discussing the case pointed out the following unusual characteristics: the occurrence of primary anemia in a Negro; the very low values, at least in the present case, for erythrocytes and hemoglobin; the extremely elevated color index and mean corpuscular volume; the manifest response to liver extract within twenty-four hours; and the lack of neurological manifestations in such a severe degree of anemia.

The second case, presented by the surgical staff was that of a forty-nine-year-old Irishman who had received a compound comminuted fracture of the lower leg from being struck by an automobile one month before. There had also been a concussion of the brain, with temporary loss of consciousness, and a back injury. On admission his blood pressure was 90 systolic, 60 diastolic, and the patient showed evidence of incipient shock. Immediate treatment consisted of a 300-cc. blood transfusion followed when the patient's condition had sufficiently improved, by amputation of the injured tissue of the leg under local and later spinal anesthesia. Red blood cells found in the urine on admission gradually diminished in the next few days. On the third day the temperature suddenly rose and the patient complained of pain in the injured member. A window was made in the cast, which revealed bloody fluid, edema and gas bubbles. Culture revealed an atypical type of *Clostridium oedematis maligni* (*Vibrio septique*) and a blood culture yielded the same organism. Therapy consisted of sulfanilamide, 6 to 12 gm. per day which resulted in a blood level of 12.2 mg. per 100 cc., and roentgen treatment to the local lesion after opening it widely. The urine then became grossly bloody and x-ray examination revealed a fractured eleventh rib. The temperature suddenly rose to 105 F., and bile appeared in the urine. Consequently chemotherapy was discontinued and 40,000 units of polyvalent gas-bacillus antitoxin was administered. The jaundice and hematuria gradually disappeared while the local condition became

one of simple staphylococcal infection. Histaminase was employed as a prophylactic against serum reaction.

In discussion, Dr. Zollinger alluded to the improvement in treatment and in prevention of the spread of the dread gas-bacillus infection since 1933 when a similar episode had provoked a hospital epidemic. Dr. Charles A. Janeway emphasized that the isolated organism was not the usual offender (*Cl. welchii*) in civilian gas-bacillus infection and differed from the latter in forming edema more than gas and in being more invasive. Although sulfanilamide was considered probably responsible for the sterilization of the blood stream in this case, its efficacy in the treatment of such cases was not considered proved. The use of antitoxin was advocated as a valuable adjunct, if not as the more important part of therapy. Dr. Janeway finally cited some pertinent experiments on guinea pigs which support this theory. The control group which received no therapy died quickly of local and general infection; those treated with sulfanilamide, although showing evidence of local infection and appearing very sick, failed to succumb to the relatively mild systemic effects of the bacilli of those treated with antitoxin, the majority exhibited neither local nor systemic evidence of gas-bacillus infection. Dr. Carl W. Walter stated that most sterilizing techniques tend to foster sporulation, a fact which increases the difficulty of controlling the infection. He advocated, instead, the immediate destruction of bacterial life with heat and the subsequent cleansing of the contaminated articles.

Dr. Walter the speaker of the evening, presented a motion picture depicting the history, rationale and technique of "Steam as a Sterilizing Agent." As a preamble Dr. Walter indicated that the concept of sterility, despite its official definition as "that which is free of viable bacterial life," was given a wide variety of meanings practically. In reviewing the historical development of the subject, allusion was made to the classic work of Oliver Wendell Holmes in 1843 and Semmelweis in 1846 on puerperal fever as a communicable disease, largely preventable by proper cleaning by attendants between confinement cases. Lister from 1860 to 1867 applied Pasteur's theories to the treatment of compound fractures and tuberculous abscesses and consequently excluded air during operation. It was von Bergmann, however, who in 1882, saw the importance of instruments and dressings as a means of contamination and advocated their sterilization preoperatively with bichloride of mercury. This was the first of effort to substitute asepsis for antiseptics. Dr. Walter then traced the practical development of steam sterilization from Koch, Gaffky and Loeffler in 1881 through Redard, the von Bergmanns, and Schummelbusch in 1891 who perfected a ritual for preoperative technique which has since persisted largely unaltered.

The theoretical development started with Globbig (1887) who recognized the importance of resistant spores, and progressed via Gruber (1888) who proposed the gravity method of air clearance, Esmarch (1888) who proved the ineffectiveness of superheated steam, Redard (1889) who demonstrated the increase of temperature by an increase of pressure, Lewin (1889) who pointed out the importance of moisture in causing protein coagulation, Teuscher (1890) who showed the retardation of sterilization by an oil coating and the importance of regulating the chamber temperature by a thermometer in the exhaust line, Forsch and Clarenbach (1890), who emphasized that the quantity of the steam available rather than its pressure determined the effectiveness of a sterilizer, Rubner (1889) who demonstrated the variation of temperature with composition of air steam mixtures in vari-

ous parts of bundles, and, finally, Prescott and Underwood, who initiated (1897) the study of the bacteriology of sterilization in the canning industry, which culminated (1923) in the stamping out of botulism.

All these findings have been recently confirmed at the Peter Bent Brigham Hospital, and consequently Dr Walter is undertaking to educate the medical profession and the lay persons who often operate sterilizing plants, both of which groups have in general failed to accept and employ these fundamental concepts of steam sterilization. The speaker supplied the dialogue for an excellent motion picture which showed the improper traditional and the proper scientific technics of steam sterilization. The problem of air clearance, which is necessary for steam to be effective as a bactericidal agent, was solved by employing only loosely packed materials in unsealed containers or porous wrappers, by placing all layered packs in such a position that a horizontal path was assured for escape of air, and by placing fluffed gauze in the wrists of unfolded rubber gloves. The efficacy of a gravity rather than a vacuum type of air ejector was demonstrated and its economic advantages cited. The proper methods for sterilizing various types of materials were described, with particular attention being focused on rubber gloves, which should be properly prepared as outlined above and put in the upper part of the chamber, for the delay and prolonged exposure otherwise entailed are definitely deleterious to the material.

Dr Walter explained charts which indicated the efficacy of moist rather than dry heat and the more effective and rapid sterilization by saturated steam than by either a stratified or homogeneous mixture of air and steam due to faulty air clearance. The effects of faulty positioning and overloading as a cause of pocketing air and preventing adequate sterilization were also demonstrated. Another mistake mentioned was the repeated short exposures used, which serve only to reheat the outer layers of any bundle without causing sufficient moistening and heating of the center.

In conclusion, Dr Walter suggested the following practical measures: the use of temperature rather than pressure as an indication of chamber steam, since an air-steam mixture may attain sufficiently high pressure, the use of a thermometer in the exhaust line to determine the prevailing chamber temperature, the use of a thermo-responsive timer, which records only with sustained temperature and so prevents repeated reheatings. The standard technic, to be carried out by a responsible personnel, should consist of the maintenance of a temperature of 250°F, as measured by the exhaust thermometer, for thirty minutes continuously, as measured by the thermo-responsive timer.

NOTICES

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent Brigham Hospital will be held on Wednesday, May 1, from 2 to 4 p.m. Drs. Robert Zollinger and Soma Weiss will speak on "Vomiting."

Physicians and students are cordially invited to attend.

BOSTON DISPENSARY

A luncheon meeting of the clinical staff of the Boston Dispensary will be held on Monday, April 29, in the auditorium of the Joseph H. Pratt Diagnostic Hospital at 12 o'clock noon. "The Boston Dispensary" will be the subject of the third in a series of talks by different speakers on the past, present and future of the New England Medical

Center and its constituent units. Mr. Charles C. Cabot will speak on "Problems of Financing and Support," and Mr. Frank E. Wing will discuss "Its Origin and Its Objectives."

MASSACHUSETTS GENERAL HOSPITAL

A meeting of the Hospital Research Council will be held in the Ether Dome of the Massachusetts General Hospital, on Tuesday, April 30, at 5 00 p.m.

PROGRAM

The Bence-Jones Protein and Pseudo-Bence-Jones Proteins. Dr. Bernard M. Jacobson.

The Significance of Enzymatic Destruction of Synovial Fluid Mucin. Drs. William V. B. Robertson, Marian W. Ropes and Walter Bauer.

The Relationship of Chemical Constitution and Anesthetic Potency to Cortical Potentials. Dr. Henry K. Beecher.

SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, May 14, at 12 o'clock noon. Dr. William B. Breed will speak on "Emergencies in Medical Practice."

Physicians are cordially invited to attend.

GREATER BOSTON MEDICAL SOCIETY

The twenty-fifth anniversary dinner meeting of the Greater Boston Medical Society will be held at the Hotel Kenmore, Boston, on Tuesday, May 7, at 6 30 p.m. Dr. Benjamin Spector and Mr. Charles E. Wyzanski, Jr., will be the speakers.

AWARDS FOR OBSERVATIONS ON EPILEPSY

Two annual awards of \$100 each are offered by the Laymen's League against Epilepsy for the best original unpublished observations or investigations bearing on the subject of epilepsy. One of these is for work done in a state epileptic colony or mental hospital, the other is for work done elsewhere. Since one object of the award is the encouragement of junior workers, the committee will take into consideration the facilities of the authors, clinical as well as laboratory studies will be welcomed. Awards will be made by a committee of three, composed of the president of the American League against Epilepsy, the chairman of the Section on Convulsive Disorders of the American Psychiatric Association, and a third physician chosen by the officers of the Laymen's League against Epilepsy. It is hoped that winning contributions will be presented before the annual joint scientific session of the first two of these organizations. At the discretion of the committee awards may be divided or postponed.

Papers for 1940 should be submitted by December 15. Further information can be obtained from the secretary of the Laymen's League against Epilepsy, Mrs. N. Bond Fleming, 25 Shattuck Street, Boston.

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children

will be held in the classroom in the nurses' residence of the hospital on Thursday, May 2, at 7 15 p.m.

Mr James T. Pugh the guest speaker will present the subject "The Legal Aspect of Medicine."

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

| CLINIC | DATE | ORTHOPEDIC CONSULTANT |
|-------------|--------|-----------------------|
| Haverhill | May 1 | William T. Green |
| Lowell | May 3 | Albert H. Brewster |
| Salem | May 6 | Harold C. Bean |
| Brockton | May 9 | George W. Van Gorder |
| Gardner | May 14 | Mark H. Rogers |
| Northampton | May 15 | Garry deN. Hough Jr. |
| Worcester | May 17 | John W. O'Meara |
| Pittsfield | May 20 | Francis A. Slowick |
| Fall River | May 27 | Eugene A. McCarthy |
| Hyannis | May 28 | Paul L. Norton |

ST FRANCIS HOSPITAL (HARTFORD) ALUMNI

The annual meeting of the intern alumni and the regular and courtesy staffs of St. Francis Hospital Hartford, Connecticut, will be held at the Wampanoag Country Club, West Hartford, on Tuesday, May 21 at 6 30 p.m.

NATIONAL GASTROENTEROLOGICAL ASSOCIATION

The fifth annual convention of the National Gastroenterological Association will be held June 4, 5 and 6 at the Hotel Roosevelt, New York City. Papers by authoritative speakers from various parts of the United States will be given during the mornings and afternoons of all three days, and each will be discussed by well-qualified physicians. The luncheons on all three days will be followed by round-table conferences. The Committee of Ladies is arranging an interesting program of social activities for the families and friends of the visiting members.

Among the scheduled speakers are Drs. C. S. Keefer, Robert Zollinger, R. B. Cattell, I. R. Jankelson and C. W. McClure, of Boston; the discussors include Drs. Carl Bearse, H. G. Dunphy, G. W. Papen and L. F. Curran, of Boston; Dr. R. F. Scholl, of New Haven, Connecticut; and Dr. L. R. Whitaker, of Portsmouth, New Hampshire.

Members of the medical profession are cordially invited to attend. More detailed information and copies of the program may be obtained by application to Dr. Henry Kendall, 16 East 96th Street, New York City.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING SUNDAY APRIL 28

MONDAY APRIL 29
12 m. Boston Dispensary. Luncheon meeting of the clinical staff. Joseph H. Pratt Diagnostic Hospital.

TUESDAY APRIL 30
9-10 a.m. The Soldier and His Heart. Dr. P. D. White. Joseph H. Pratt Diagnostic Hospital.
5 p.m. Hospital Research Council, Massachusetts General Hospital.

WEDNESDAY MAY 1
9-10 a.m. Hospital case presentation. Dr. J. E. Paullin. Joseph H. Pratt Diagnostic Hospital.
7-8 p.m. Vomiting. Drs. Robert Zollinger and Soma Weiss. Peter Bent Brigham Hospital.

THURSDAY MAY 2
9-10 a.m. Clinicopathological conference. Dr. C. S. Keefer. Joseph H. Pratt Diagnostic Hospital.
7 15 p.m. The Legal Aspect of Medicine. Mr. James T. Pugh. New England Hospital for Women and Children.

FRIDAY MAY 3

9-10 a.m. A Review of Diabetes. Dr. E. P. Joslin. Joseph H. Pratt Diagnostic Hospital.

SATURDAY MAY 4

9-10 a.m. Hospital case presentation. Dr. J. E. Paullin. Joseph H. Pratt Diagnostic Hospital.

Open to the medical profession.

May 5—Boston Doctors' Symphony Orchestra concert. Page 687 issue of April 15.

May 7—Greater Boston Medical Society. Page 736.

May 9—Pentucket Association of Physicians. 8:30 p.m. Hotel Bartlett, Haverhill.

May 10-13—American Scientific Congress. Page 1043 issue of December 28.

May 13—United States Pharmacopoeial Convention. Page 202, issue of February 1.

May 14—South End Medical Club. Page 736.

May 15—St. Francis Hospital (Hartford) alumni. Notice above.

May 21-22—Massachusetts Medical Society Annual meeting, Boston.

June 4-6—National Gastroenterological Association. Notice above.

June 4-7—American Association of Industrial Physicians and Surgeons. Page 634 issue of April 11.

June 7-8—American Heart Association. Page 469 issue of March 14.

June 7-10—American Board of Obstetrics and Gynecology. Page 606, issue of April 4.

June 8 and 10—American Board of Ophthalmology. Page 719 issue of November 2.

June 10-14—American Medical Association. Annual meeting, New York City.

June 10-14—American Physicians' Art Association. Page 332 issue of February 21.

June 23-25—Maine Medical Association. Annual meeting, Bangor, Lakes.

October 8-11—American Public Health Association. Page 655 issue of April 11.

October 21—American Board of Internal Medicine, Inc. Page 369 issue of February 29.

DISTRICT MEDICAL SOCIETIES

ESSEX SOUTH

May 8—Annual meeting. Salem Country Club, Peabody.

FRANKLIN

May 14—Franklin County Hospital, Greenfield.

HAMPSHIRE

May 8, at 11:30 a.m. at the Cooley Dickinson Hospital, Northampton.

MIDDLESEX EAST

May 15 at 12:15 p.m. at the Unicorn Country Club, Stoughton.

MIDDLESEX NORTH

July 31

October 30.

NORFOLK SOUTH

May 2.

BOOK REVIEWS

New Ways in Psychoanalysis Karen Horney 313 pp.
New York: W. W. Norton & Co., Inc., 1939 \$3.00

This is a thoughtful volume written by an analyst of many years' experience. It discusses many complicated questions in the recent development of psychoanalysis. Any attempt to evaluate the volume must take into consideration Freud's various revisions of his original views in the light of further clinical observations. Like many scientific disciplines, the theory and technique of analysis have undergone changes within the last fifty years. For

instance, its former rather static concepts have given way to a more dynamic viewpoint, particularly since the functions of the ego and its aberrations have become more clearly understood. Psychoanalysis began with a biological orientation as a genetic instinct psychology, at present, it is both biological and sociological in its presentations and technic. The original, basic ideas have remained, but newer discoveries and observations are being given greater prominence due to increased clinical experience.

It seems that the purpose of Dr. Horney's book is an attempt, as she claims, to rid psychoanalysis of the heritage of the past so that its greater potentialities may develop and thus make a critical evaluation of both psychoanalytic theory and therapeutic technic. She states, for instance, "the purpose of this book is not to show what is wrong with psychoanalysis but through eliminating the debatable elements to enable psychoanalysis to develop to the height of its potentialities." Of course, psychoanalysis is a new science, many of its problems remain unsolved, consequently, her emphasis on this point is not new, as no analyst today believes that psychoanalysis is a finished product.

She emphasizes environment as responsible for creating neurotic conflicts and, in addition, insists on other clinical factors in the genesis of the neuroses. For instance, she believes that sexual difficulties are the effect rather than the cause of neuroses. She claims that the aim of analytic therapy is to lessen the anxiety of the patient and not gain mastery over instinctual drives.

In the course of the volume, she criticizes Freud's biological orientation and claims that he remained an instinct theorist, consequently she insists that neurotic conflicts are also determined by cultural and environmental conditions. She discards the theoretical implications of the Oedipus complex and seems to overlook the fact, even with her sociological orientation, that this complex is the first social experience of the child. Freud in 1923, in a paper on a neurosis of demoniacal possession occurring in the seventeenth century, understood the sociological implications of the neuroses and, furthermore, Ferenczi and Rank, in 1925, emphasized this social aspect of psychoanalysis.

The reviewer believes that it is impossible to make a gap between social setting and either psychological or biological setting. This is shown by the fact that neuroses may assume different clinical forms under different cultural conditions. According to Dr. Horney the patient's neurotic difficulty is a compulsory need to appear perfect, whereas according to Freud it is the unconscious feelings of guilt which form the main obstacle to the cure of the severe neuroses. She maintains that Freud's work has certain limitations in the understanding of cultural factors and that he remained an instinct theorist. In reply to this viewpoint it can be stated that the symptoms of the neuroses, besides being cultural or sociological in nature, are also psychological, cultural conditions are produced by instinctual drives and, inversely, instinctual drives produce cultural patterns. According to her, also, anxiety, which is an essential symptom of every neurosis, is frequently the result of being in some acute dilemma without being aware of it, whereas, according to Freud, the therapy of anxiety is a search for repressed drives and ego defenses. Her insistence on active therapy in analysis is not new, since this procedure has been utilized for some years. The important aim of therapy is to carry the analysis along until the patient can find a satisfactory solution in his life situation.

It must be emphasized that psychoanalysis began as a medical discipline and still remains so, and her challenge that it neglects the social aspect of the neuroses is merely

her own insistence on revision, which, when the book is carefully read, is not so revolutionary as the uninformed reader might be led to believe. For instance, her statement that anxiety in the neuroses is the result of the failure of the specific safety devices of the ego to operate, but another way of stating that this anxiety is due to weakening of the defenses of the ego, from whatever cause.

A History of Tropical Medicine Based on the Fitzpatrick Lectures H. Harold Scott. 2 vol. 1165 pp. Baltimore: William Wood & Co., 1939. \$12.50 per set.

These volumes are based on the Fitzpatrick Lecture given by the author. He begins with an account of the slow progress of hygiene at sea and in the military service in the eighteenth and nineteenth centuries and, to complete the background, discusses early conditions in some of the British dependencies. Subsequent chapters are devoted to the principal tropical diseases. Their history is traced in detail to the earliest available records.

The accounts of malaria, yellow fever and the avitaminoses are likely to be of special interest to Americans. With reference to malaria in America, the statement is made (page 128) that "it is the general belief that malaria was originally introduced either from Europe or by the slaves from Africa." Although the reviewer shares this opinion, he doubts that it has received wide acceptance.

A long chapter on yellow fever scarcely mentions Carter's important contribution to the history of this disease (*Yellow Fever: An epidemiological and historical study of its place of origin*, Baltimore: Williams & Wilkins, 1931) but in other respects it is admirable. The chapter on the avitaminoses is devoted largely to beriberi, the early history is excellent, but the progress of the past ten years is not mentioned. A short chapter on the Panama Canal, another on the slave trade with reference to disease, and a series of short biographies of persons who have made great contributions to the subject of tropical medicine are likely to prove of general interest.

The reviewer is impressed with the magnitude of the task undertaken by the author and with the success which he has achieved in providing a most useful book of reference.

The International Medical Annual: A year book of treatment and practitioner's index. Edited by H. Leubke, Tidy and A. Rendle Short. Fifty seventh year. 602 pp. Baltimore: Williams & Wilkins Co., 1939. \$6.00.

This annual is in its fifty seventh year. The book covers the whole field of medicine as viewed by numerous English authors. There is the usual general index, and a series of excellent illustrations from a wide variety of publications. The reviews are carefully done, and this is an important addition to the medical literature which aids the physician in keeping abreast of rapidly advancing medical research.

Les Embolies Cérébrales: Études de pathologie expérimentale sur les embolies solide et gazeuse du cerveau. Maurice Villaret and René Cachera. 134 pp. Paris: Masson et Cie, 1939. 32 Fr. fr.

This is a treatise in regard to experiments concerning the pathology of embolism of the brain. The authors have worked largely with dogs and have taken advantage of the cerebral window for the observation of the vessels in the living animals, as developed by Forbes at the Harvard Medical School. It is a valuable work in a small field.

CLINICAL AND LABORATORY STUDIES ON THE USE OF SERUM AND SULFAPYRIDINE IN THE TREATMENT OF THE PNEUMOCOCCAL PNEUMONIAS*

MAXWELL FINLAND, M.D.,† FRANCIS C. LOWELL, M.D.,‡ AND WILLIAM C. SPRING, JR., M.D. §

BOSTON

AMONG the recent reports on the treatment of pneumococcal pneumonia, those which emanated from clinics where both specific serums and sulfapyridine were used extensively have shown that each of these two agents is highly effective. Most of the workers, however, have agreed that a definition of the conditions under which the use of serum alone, sulfapyridine alone or the combination of the two will give the optimum benefit must await the accumulation of a large amount of data subjected to detailed and critical analysis. In this paper we present a résumé of the results of laboratory and clinical studies bearing on this subject which were conducted at the Boston City Hospital during 1938-1939. The details of these studies are reported elsewhere.¹⁻⁴

LABORATORY INVESTIGATIONS

These concerned the mode of action of sulfapyridine on pneumococci and the significance of antibody in this action, the humoral antibody response of sulfapyridine-treated patients and the absorption, excretion and distribution of sulfapyridine. A number of these observations merely confirm and extend the results of similar studies reported by other workers. Our results will be summarized briefly.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard) Boston City Hospital, and the Department of Medicine, Harvard Medical School, Boston.

Technical assistance was given in the bacteriological and immunological studies by Mildred W. Barnes and Clara Wilson; in the pneumococcus typing by Kathleen Daley and Winifred Doyle; and in the chemical determinations by Margaret A. Adams and Nancy E. Mearns. The studies were made possible through the generous co-operation of the resident and visiting staffs of all the medical services and of the Mallory Institute of Pathology of the Boston City Hospital. The serums were furnished by the Lederle Laboratories, Inc., Pearl River, New York; the Massachusetts Antitoxin and Vaccine Laboratory; and E. R. Squibb and Sons, New York City. The sulfapyridine was furnished by the Lederle Laboratories, Inc., the Calco Chemical Company, Newark, New Jersey and Merck and Company, Rahway, New Jersey.

Action of Sulfapyridine and Antibody*

Pneumococci were grown at 37°C in favorable artificial mediums, in human blood lacking pneumococcal properties and in each of these mediums after varying concentrations of sulfapyridine had been added. The resulting bacterial populations were determined at varying intervals. Both with and without sulfapyridine the initial parts of the growth curves over a period of four hours, and in some cases even up to eight hours, were found to be identical. Multiplication always took place and the population increased from tenfold to a thousandfold during this period. After four to eight hours the shape of the growth curve, indicating either continued growth, bacteriostasis or decline in population, depended mainly on three factors: the size of the original inoculum, the concentration of the drug, and the susceptibility of the strain of pneumococcus used. With large original inocula, the bacterial population either remained static or declined slowly over a period of three or four days. With smaller inocula this static phase lasted only four to eight hours and was followed by a comparatively rapid decline in the numbers of viable organisms, so that none could be recovered in subcultures made after eighteen to forty-eight hours. Concentrations of sulfapyridine of 10 mg per 100 cc. usually resulted in complete sterilization of the mediums within twenty-four to forty-eight hours, with original populations up to 10,000 diplococci per cubic centimeter, while a sulfapyridine concentration of 5 mg per 100 cc. resulted in a decline in population after eight hours only when very small inocula (10 organisms or less per cubic centimeter) were used. In some experiments with Type 3 pneumococci and human blood, 10 organisms per cubic centimeter multiplied a hundredfold to a millionfold in the presence of a sulfapyridine

concentration of 5 mg per 100 cc, and the population then remained static for forty-eight hours or longer (Fig 1) In some cultures, even with sulfa-

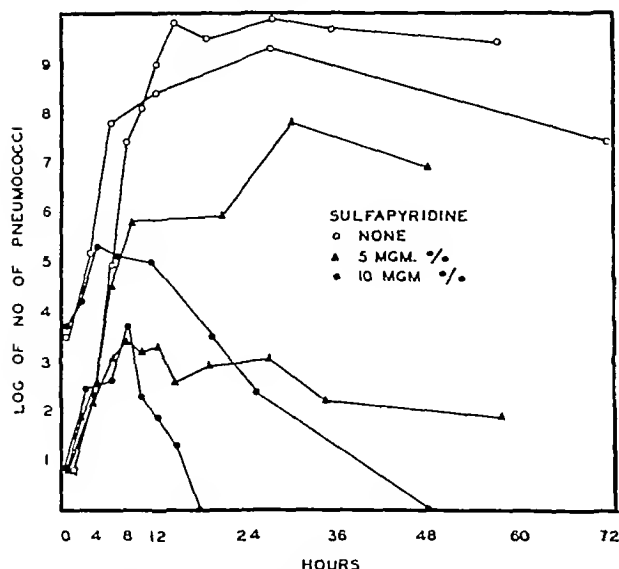

FIGURE 1 *Growth of Type 3 Pneumococci in Fresh Normal Defibrinated Human Blood That Lacked Pneumococidal Properties*

pyridine concentrations of 10 mg per 100 cc., the decline in bacterial population of the culture stopped after about twenty-four hours, and was followed first by a static phase and then by a second growth phase. The latter phenomenon may have been due to the development of sulfapyridine-fast variants within the culture,⁶ although this was not determined.

The results were quite similar with all the strains used, although there were some variations in the rate of growth and in the maximum populations attained, particularly with recently isolated strains. In every case bacteriostasis or killing of pneumococci attributable to sulfapyridine occurred only after multiplication of bacteria had taken place in the presence of the drug. Exposure of the bacterial cultures at a temperature of 5°C during any phase resulted in a suspension of growth and of sulfapyridine action, and these activities were resumed apparently unaltered when the culture was again incubated at 37°C. At 27°C growth, stasis and killing were slower than at 37°C. At 40°C the activity was approximately the same as at 37°C for forty-eight hours. Peptone, 2 per cent, in the medium had no significant effect on the sulfapyridine action. Soluble specific substance sufficient to inhibit the pneumococidal action of large amounts of the homologous antibody did not interfere with the bacteriostatic or bactericidal action of sulfapyridine.

Tests were also carried out with sulfanilamide and sulfapyridine in fresh defibrinated blood from patients with pneumococcus Types 1, 3 and 5 pneu-

monias, when such blood lacked pneumococidal action against the homologous pneumococcus. In these bloods, sulfanilamide in concentrations of 5 mg per 100 cc or higher inhibited the free growth of moderate numbers of pneumococci. Complete sterilization of the blood with sulfanilamide occurred infrequently, and then only with small original inoculums and with concentrations of 20 mg per 100 cc. The latter action was duplicated by sulfapyridine in concentrations of 5 mg per 100 cc or even less. With 7.5 mg per 100 cc or more of sulfapyridine, free growth was inhibited when as many as 100,000 or 1,000,000 pneumococci were inoculated in 0.5 cc. of blood, and no organisms could be grown in subcultures made at forty-eight hours when 1000 or even 10,000 diplococci were inoculated in the same amount of blood.

Type-specific antibody contained in therapeutic horse and rabbit serums induced marked pneumococidal action in the blood of the pneumonia patients. The combined action of small concentrations of sulfapyridine (25 mg per 100 cc.) and small amounts of the specific antiserums produce greater pneumococidal action than that occurring when the same amount of either of these agents was used separately.

In studying the bactericidal action of human blood it was found possible to distinguish between

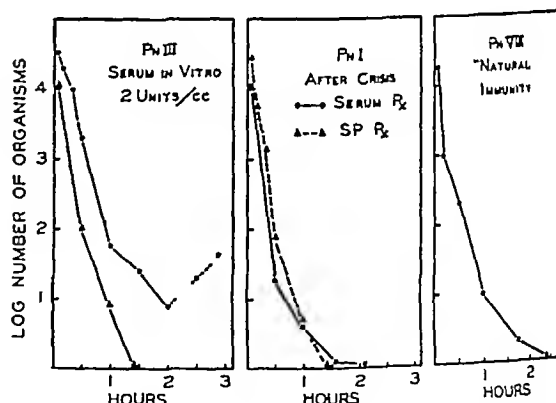

FIGURE 2 *Pneumococidal Action of Freshly Shed Fibrinated Human Blood, Incubated at 37°C*

In the first panel, the two curves represent separate tests. In the second panel, the curves represent tests with serums from two different patients, one who had serum therapy and the other sulfapyridine therapy.

the action due to the drug and that due to immune substances—both the so-called “natural” antibody or the antibody acquired either actively as a result of the infection or passively following serum injections. Pneumococidal action due to immune bodies occurred rapidly and was usually carried to completion within two or three hours (Fig 2). During this time the static phase of sulfapyridine

action is not yet reached and organisms are still multiplying in the absence of an immune mechanism (Fig 1)

These findings may be interpreted as indicating that both specific antibody and sulfapyridine have important but entirely distinct modes of action. The former has been shown to require an adequate number of intact phagocytic cells and also a heat labile serum factor (complement)², the latter does not require the mediation of serologic or cellular elements. In addition, the action of serum is rapid and is carried to completion, at least in vitro, before active growth in the presence of sulfapyridine is expected to cease. It seems reasonable that if both these mechanisms could be brought into play in the patient undergoing treatment for pneumonia, their actions might supplement one another and prove of great benefit, particularly to the heavily infected patient.

Antibody Response of Sulfapyridine Treated Patients³

Tests for bactericidal action, opsonins, mouse protective antibodies and agglutinins for the homologous type of pneumococcus were carried out with the blood of patients taken before, during and after treatment with sulfapyridine. Some of these patients also received specific serums at varying intervals after treatment with the drug had been begun. A considerable number of patients had varying amounts of pneumococidal power in their bloods before any treatment was given, but mouse protective antibodies were rarely found and agglutinins were not demonstrated at this time.

During sulfapyridine treatment, the blood of patients showed marked bacteriostatic and considerable bactericidal action on the homologous type of pneumococcus. This action was independent of the immune mechanism, and was the same as that induced by comparable concentrations of sulfapyridine when added to artificial mediums or to human blood in vitro. By doing bacterial counts in the blood two or three hours after inoculation, it was possible to differentiate pneumococidal action due to the drug and that due to antibody—whether natural,⁴ spontaneously acquired or passively introduced by therapeutic serums. Only antibodies gave rise to pneumococcus killing within two or three hours. The greatest and most rapid pneumococidal action occurred in the presence of heat stable antibodies (agglutinins, mouse protective antibodies, opsonins). Such antibodies appeared at about the same time that they would be expected to develop in patients who recover spontaneously. Protective antibodies rarely developed before the sixth day and agglutinins rarely appeared before the seventh day of the disease, irrespective of the time when the fever and pulse rate returned to

normal. When specific serum was given intravenously, a balance of all the antibodies measured was established and readily maintained in the circulating blood.

These findings again suggested that the combination of specific antibody and sulfapyridine was the most advantageous therapy in cases of pneumococcal pneumonia.

Fate of Sulfapyridine and Related Compounds in the Body

These studies were carried out in collaboration with Dr F H L. Taylor and his associates, at the Thorndike Memorial Laboratory. They included determinations of the concentration of the drug in the blood, and in some cases in the body fluids, of patients under treatment with sulfapyridine orally or with its sodium salt intravenously, similar and more detailed studies following the administration of single doses of sulfapyridine and of related compounds given by various feasible routes, a study of the distribution of these drugs between serum and red blood cells, and their distribution in the body fluids and organs in patients who died during treatment.

The absorption, excretion and degree of acetylation of sulfapyridine varied widely in different patients receiving the same dose of the drug.⁵ Such factors as fever, body weight, water exchange, vomiting, toxemia, nutritional deficiency states and impairment of renal function may have accounted for some of the variations observed, but many of them could not be explained. Nitrogen retention and other evidences of renal failure were most regularly associated with high levels of sulfapyridine in the blood and delayed excretion in the urine. This was usually, but not regularly, associated with a high percentage of acetylated drug in the blood. More than 60 per cent of the ingested drug was recovered from the urine in orally treated cases. The proportion excreted as the unconjugated drug varied considerably.

After a single oral dose of sulfapyridine, the maximum blood concentration was reached in about six hours, and the levels thereafter declined somewhat more slowly than they did when the intravenous route was used. About 80 per cent of the drug was recovered in the urine, excretion continuing for about five days. About half the amount was excreted in the first twenty four hours, and about 75 per cent of the chemical in the urine was in the acetylated form.

It was possible to establish and maintain satisfactory concentrations of sulfapyridine in the blood by the intravenous injection of its sodium salt, either exclusively or as a supplement to oral therapy. When a single dose of sodium sulfapyridine was given intravenously, the maximum concentra-

tion was attained in the blood at the end of the injection. At this time almost all the drug was circulating as free (unconjugated) sulfapyridine. The concentration in the blood declined rapidly at first and then more slowly. The percentage of drug circulating in the conjugated form increased steadily, so that little or no free sulfapyridine was detectable in the blood after twenty-four hours, while appreciable amounts of the acetylated drug could be found during the next twenty-four hours or even longer. The drug appeared rapidly in the urine. The specimens voided during the injection contained a small percentage of drug as acetylated sulfapyridine, and later ones contained increasing proportions of the chemical in this form. More than 60 per cent of the drug was excreted in the urine within twenty-four hours, but the excretion continued for about ninety-six hours, during which time about 90 per cent of the amount injected was recovered. Of the amount excreted, about 75 per cent was acetylated. The drug was excreted rapidly into the stomach and appeared in the gastric contents in greater concentrations than in the blood. Its appearance in the spinal fluid was somewhat delayed, reaching about half the blood concentration in one to three hours after the intravenous injection.

Sulfapyridine is relatively insoluble, but it was possible to get considerable amounts of the drug into complete and stable solution in 50 per cent glucose. This required boiling for a few minutes, when apparently a new compound was formed. Such a solution, containing the equivalent of 10 per cent sulfapyridine, could be given intravenously, subcutaneously (when diluted to the isotonicity of glucose) and orally without untoward effects. After the intravenous injection of this glucose sulfapyridine solution the initial concentrations of drug in the blood were higher than those after the injection of equivalent amounts of sodium salt. It was also eliminated much more rapidly, so that it could not be detected in the blood after twelve hours and very little was found in the urine after twenty-four hours. It was also eliminated much more rapidly after subcutaneous injection than were equivalent amounts of sulfanilamide. *When used in vitro, however, or after its parenteral administration, this glucose sulfapyridine solution was found to be essentially inert in bactericidal tests*⁸. Oral administration of glucose sulfapyridine resulted in markedly delayed absorption, the maximum blood levels being attained after twenty-four to thirty-six hours. The drug found in the blood after its oral administration was found to be active in bactericidal tests.*

Blake's solution made by adding 2 gm. of sulfapyridine to 500 cc. of 5 per cent glucose which has been brought to a boil and then adding 500 cc. of physiological saline retains sulfapyridine activity provided that it is not boiled after the drug is added.

Sulfapyridine was found to distribute itself rapidly and uniformly between serum and blood cells. This was true when it was added *in vitro*, after oral administration or after the intravenous injection of its sodium salt. Sulfanilamide, as also shown by Sise,¹⁰ was found in slightly greater concentration in the red blood cells than in the serum under these circumstances. Glucose sulfapyridine, when added to blood *in vitro* or when found in blood after parenteral administration, failed to enter the blood cells and could be recovered entirely from the serum. In the body, the glucose sulfapyridine was distributed only in the extracellular fluid, whereas sulfapyridine and sulfanilamide were distributed throughout the total body water. The renal clearance of these compounds indicated considerable reabsorption of sulfanilamide and sulfapyridine by the tubules, but there was no reabsorption after glucose sulfapyridine was given parenterally. Glucose sulfapyridine given orally behaved like sulfapyridine except for delayed absorption.

In the course of therapy the concentrations of sulfapyridine, both free and conjugated, were always found to be lower in pleural exudates and in cerebrospinal fluids than in the blood taken at the same time. Spinal-fluid levels were relatively lower than pleural-fluid levels. We also had an opportunity to study the concentration of sulfapyridine and sulfanilamide in various body fluids and organs of patients who died while under treatment with this drug. None of the patients had crystals or concretions in the urinary tract. The results indicated a more or less uniform distribution of the drugs in most organs. The brain and spinal fluid had lower concentrations than did the blood. There was marked concentration of drug, particularly in the acetylated form, in the urine. In the kidneys of the sulfapyridine-treated cases the concentration of drug was two or more times as great as in the other organs. In the kidneys of the small number of sulfanilamide treated cases that were examined the concentration of drug recovered was about the same as that of the blood.¹¹ This difference between sulfanilamide and sulfapyridine may reflect an important difference in the way these two drugs are handled by the kidney.

CLINICAL RESULTS

At the Boston City Hospital from July 1, 1938 to July 1, 1939, there were 1037 patients over twelve years of age who had acute parenchymatous pulmonary infections associated with the finding of type-specific pneumococci. Concentrated anti-pneumococcus horse and rabbit serums were used in some of the cases throughout the season. Sulfapyridine was first used in the latter part of Oc-

tober, but only a limited supply of this drug was available for several weeks. Its use was limited at first to mild cases and to those with higher types of pneumococci or with mixed infection. Later the use of the drug was extended in an effort to determine its full range of effectiveness. Patients started on sulfapyridine therapy were later given serum if they did not tolerate the drug well or if the response was not satisfactory. The combination of serum and sulfapyridine was used in some of the severest cases, treatment with these agents was started simultaneously in some cases

specific serums, have been studied in a more or less uniform manner in this hospital for several years and many of the data on these cases are available for comparison.¹² Only the more important facts brought out in this study can be summarized here. The detailed analysis is presented elsewhere.¹

Mortality in Relation to the Incidence of Important Prognostic Factors

The serum-treated cases had the lowest death rate (Table 1). As compared with the cases treated

TABLE 1 *Incidence of the Important Prognostic Factors in Cases of Pneumococcal Pneumonia and Their Effect on the Mortality (July 1 1938 to July 1 1939)*

| DATA | TYPE OF THERAPY | | | | ALL CASES |
|---------------------------------------|-----------------|-------------------------|---------------|----------------------------|-----------|
| | SERUM | SERUM AND SULFAPYRIDINE | SULFAPYRIDINE | NO SERUM, NO SULFAPYRIDINE | |
| Number of cases. | 211 | 129 | 225 | 472 | 1037 |
| Incidence | % | % | % | % | % |
| Bacteremia | 28 | 57 | 23 | 7 | 22 |
| Forty years of age or over | 39 | 68 | 65 | 62 | 55 |
| Sixty years of age or over | 7 | 29 | 32 | 30 | 25 |
| More than one lobe involved | 25 | 58 | 32 | 40 | 37 |

| Seventh day or later | 27 | 45 | 34 | 29 | 33 |

and consecutively in others. No attempt was made to carry out any strictly controlled alternation, since previous experience has convinced us of the futility of such attempts when therapeutic agents with known lifesaving properties are available. A large proportion of the cases received neither serum nor sulfapyridine. These included mild cases, some which were admitted late in the disease, others in which the diagnosis was first made at autopsy, and many in which the pneumonia complicated other serious illnesses (secondary pneumonias). Sulfanilamide was used in the treatment of some of the latter group and also in a few patients who received serum, but the effect of this drug was not enough to warrant separate consideration. All the 1037 cases were chosen for analysis since similar cases, treated with or without

with sulfapyridine alone, those receiving serum alone included more bacteremic cases, but in most other respects they formed a more favorable group. More of the serum recipients were treated early, fewer had multilobar involvement or atypical or secondary pneumonias, and the percentage of cases in the older age groups was lower.

The higher death rate among the cases treated with the combination of serum and sulfapyridine is somewhat deceptive. This group included the greatest proportion of cases which, among the typical primary pneumonias, had the worst prognosis. Bacteremia and multiple lobe involvement were twice as frequent as among the cases treated with either serum or sulfapyridine alone. Either of these factors alone is enough to account for the high death rate. Furthermore, many of the cases

are included in this group because they were showing no apparent benefit from treatment with one of these remedies at the time when treatment with the second agent was started

The mortality in the cases which received neither serum nor sulfapyridine was lower than in previous years¹² This was due in large measure to the fact that severe typical cases, when recognized, were promptly treated, leaving a group of cases with more atypical and relatively milder infections, as indicated by the low incidence of bacteremia

Considering these data alone, it is fair to say that the combination of serum and sulfapyridine was the most effective treatment in the worst cases and that, taking the cases as a whole and considering the important prognostic factors, no definite superiority was demonstrated for the one agent over the other when used separately It seemed necessary, therefore, to determine if possible whether there were any special conditions in which treatment with serum or sulfapyridine, or both, was most advantageous The more detailed analyses of the cases¹ brought out a number of such conditions, some of which may be mentioned briefly

Types of pneumococci Sulfapyridine was apparently effective against all types of pneumococci In some Type 2 and Type 5 cases, particularly the former, the response to treatment with sulfapyridine alone seemed less striking than that in other types, and the combination of serum with the drug gave the best results In Type 3 cases serum alone did not seem to be effective except in the milder cases, and in these sulfapyridine was equally effective The drug was most effective in the severe cases, but a more rapid recovery occurred if it was used in combination with serum Six bacteremic Type 3 patients recovered during the season All received sulfapyridine and one received serum in addition Sulfapyridine was most advantageous in the nonbacteremic cases associated with the higher types of pneumococci, particularly when sputum was the only source of pneumococci This was especially true when the specimens examined were not entirely satisfactory, when the number of pneumococci were few or when multiple pneumococcal types or large numbers of other organisms were found

Bacteremia The mortality in all the bacteremic cases appeared to be the same, regardless of whether serum or drug or both were used There were two conditions, however, in which the combination of serum and sulfapyridine was definitely superior in the presence of bacteremia, namely, when it occurred in patients over fifty years of age, and when the cultures yielded twenty-five or more colonies per cubic centimeter of blood These, of

course, are the cases with the gravest prognosis.

During this period, as in previous years, bacteremia rarely developed or persisted once serum treatment was instituted, except in cases with a severe focal purulent complication or with endocarditis. Although this was also true in general for cases treated with sulfapyridine alone, several patients had positive blood cultures up to twenty four hours or even longer after drug treatment was begun In some of the latter cases, the cultures made before treatment with the drug was started were sterile.

Age In the present cases, as in those previously reported,⁸ specific serum alone did not seem to influence greatly the mortality in the oldest age groups, that is in patients over sixty years of age In this group, sulfapyridine was apparently effective alone in the milder nonbacteremic cases, particularly in those due to the higher types of pneumococci As already noted, the combination of serum and the drug was the most effective in the older patients with bacteremia

Time of beginning treatment Serum, with or without sulfapyridine, was the most effective therapy when treatment was begun early, that is on or before the fourth day Sulfapyridine was apparently more effective than serum if treatment was begun on the fifth or sixth day To be sure, the figures, as shown in Table 1, are somewhat deceptive, since a number of the patients who were started on sulfapyridine therapy on the fifth and sixth days and failed to show a satisfactory response were later given serum, and thus were taken out of the sulfapyridine-treated group and included among cases treated with serum and drug The cases treated after the sixth day had a lower death rate and a more rapid recovery if serum was given, with or without sulfapyridine, particularly if the blood culture was positive before treatment was begun Whenever the combination of serum and drug was used, the best results were obtained when treatment with both was begun simultaneously or when serum treatment was begun within twelve hours after the first dose of drug was given.

Extent of lung involvement If the pneumonia had already extended to involve more than one lobe at the time therapy was started, the combination of serum and sulfapyridine was the most effective therapy This was true both in bacteremic and nonbacteremic cases

Atypical pneumonias and secondary pneumonias Such cases, when due to pneumococci, have usually had higher death rates than have cases of typical primary lobar pneumonia, in spite of a higher incidence of bacteremia in the latter groups¹³ In the present series, the results of therapy in the atypical pneumonias and in those complicating other serious

illness (secondary pneumonias) were not very satisfactory regardless of the treatment used.

Duration of Acute Illness

The duration of fever, elevated pulse rate and other symptoms of the acute pulmonary infection after the beginning of treatment was twice as long in the cases receiving sulfapyridine alone as in those treated with serum, regardless of whether they received sulfapyridine in addition. This was especially true in the bacteremic cases which recovered. In such cases the average duration of fever after the first dose of serum was about twenty hours, as compared with fifty hours after the first dose of sulfapyridine when used without serum. In general, the subjective and objective improvement which followed the drop in fever was striking when serum was used, whereas patients receiving sulfapyridine continued to feel depressed and ill for some time after the fever and pulse rate had reached normal. Rusty sputum was frequently raised after this time, and the pulmonary lesion extended in some cases while the drug therapy still was being maintained.

Complications

Septic focal complications were relatively most frequent among the patients treated with both serum and sulfapyridine. This was to be expected from the higher incidence of bacteremia in this group.¹² Only a few of the more significant facts need be mentioned. Empyema was demonstrated in 9 patients treated with serum alone and in the same number treated only with sulfapyridine—an incidence of about 4 per cent in each group. There were 2 deaths among each of these 9 cases. Five of the serum-treated and 3 of the sulfapyridine-treated patients who developed empyema had positive blood cultures before treatment was begun. Among the patients who received both serum and sulfapyridine, 12 (9 per cent) developed empyema, all had positive blood cultures before treatment, and 5 died. There were 7 with empyema among the patients who received neither serum nor sulfapyridine. None of them had positive blood cultures, and 3 died. In each of the four groups, only 1 patient among those who recovered was successfully treated by repeated thoracenteses alone; the others all required surgical drainage (closed thoracotomy or rib resection).

It is also of interest that 2 patients with fibrinous pericarditis recovered. Both received serum and 1 received sulfapyridine in addition. In 1 patient treated with sulfapyridine alone, purulent meningitis apparently developed during the course of treatment. Severe secondary hemolytic streptococcus infections, usually with organisms recovered

from the blood, were relatively frequent, but less so in patients treated with sulfapyridine alone. Early relapse was not frequent. This occurred about as often in the serum-treated patients (3 cases with 2 deaths) as in those treated with sulfapyridine alone (4 cases with 1 death). The same type of pneumococcus was recovered on admission and during relapse in each of the latter cases, and different types were found in each of the serum-treated cases.

Dosage

Serum was given intravenously in divided doses, the total amount being estimated according to the type of pneumococcus, the age of the patient and the severity of the disease. The average total amount per patient was 182,000 units in those treated with serum alone, and 253,000 units in those who received sulfapyridine in addition. No attempt was made to determine the smallest effective dose, so that large excesses were usually given, particularly in bacteremic cases. The amount of antibody per patient was smaller with rabbit serums than with horse serums, although a severer group of cases was chosen for treatment with the former. The average concentration of antibodies in the rabbit serums was about twice as great as in the horse serums, so that considerably smaller volumes were necessary when the former were used.

The dosage of sulfapyridine used averaged 20 gm per patient, given over a period of about three and a half days. This was the same whether or not serum was used in addition. However, smaller total doses of the drug were used more frequently in conjunction with serum treatment. In general, each patient was given an initial dose of 2 gm. and then 1 gm. every four hours, this was continued, whenever feasible, until the acute infection seemed to be overcome, usually about forty eight hours after the temperature and pulse rate returned to normal. Severely ill patients received a second dose of 2 gm two hours after the first dose. In occasional patients the treatment was begun with an intravenous injection of the soluble sodium salt, 4 or 5 gm being given in normal saline, either in a 5 per cent solution given in ten to fifteen minutes or in 1 per cent solution, taking about an hour for the injection. Some of the patients received a second injection of the same or smaller amount after four or five hours.³

Untoward Effects

Serum reactions of the usual types were encountered but rarely were severe. With rabbit serums, chills were slightly more frequent than they were with horse serums, but immediate allergic re-

actions were much less frequent and serum sickness occurred somewhat less frequently with the former. There was a marked variation in the chill-producing properties of different lots of serum from the same laboratory, but greater differences were noted among the serums from different laboratories.

The toxic effects attributable to sulfapyridine were about the same as those reported from other clinics. Nausea and vomiting were most frequent and occurred in about two thirds of the patients. Anemia, acute and delayed, leukopenia occurring early in the course of treatment, hematuria, nitrogen retention, mental depression or marked excitement, morbilliform eruptions and drug fever were observed, but were all relatively infrequent. The renal complications were sometimes serious. Nausea and vomiting and chills sometimes occurred during or after intravenous injections of the sodium salt. One patient with incipient delirium tremens may have died as a result of a convulsive seizure followed by coma and respiratory failure that began during an intravenous injection.

Sulfanilamide

Sulfanilamide in full dosage was used in the treatment of the acute pneumonia in 106 cases. Of these, 72 received no other specific therapy and 34 received serum in addition. There were 20 deaths among the former and 12 among the latter. Only 7 of the former patients had positive blood cultures and 6 of them died, while 14 of those who also received serum had positive blood cultures and 10 of them died. Dramatic recoveries attributable to sulfanilamide, comparable to those observed under sulfapyridine therapy, were rare.

COMMENT

It is sometimes hazardous to translate, in terms of the patient ill with pneumonia, the results of experiments made with the pneumococcus in vitro or in laboratory animals. Nevertheless, the results of the laboratory studies that have been summarized here, if they are of any significance in the human disease, suggest that in general the optimum therapy for pneumococcal pneumonia should include both specific serum and sulfapyridine. When considered in conjunction with the various factors in the host and in the invading organism, the laboratory findings have helped us interpret many of the clinical results observed in individual cases and in certain groups of cases. We may cite, as an example, the treatment of aged individuals with pneumonia.

In old patients it is necessary to use the greatest caution with both serums and drugs, since the indiscriminate use of either agent may prove seriously detrimental, while the judicious use of both

may be expected to give the best results. Many patients over sixty years of age do not seem to tolerate sulfapyridine therapy, in the usual doses given, over the long period usually required in severe cases. Likewise, large doses of serums, particularly horse serums, may give rise to serious cardiovascular reactions other than those resulting from the ordinary chills or allergic reactions. Such patients, however, when seen early in the disease may have mild infections which respond rather rapidly to treatment with sulfapyridine alone. When this is true, the prolonged use of the drug, at least in full doses, is usually unnecessary, may be harmful and therefore should be avoided. In old patients under sulfapyridine treatment, kidney function is more readily impaired than it is in young patients, and the cerebral and gastrointestinal complications may prove much more serious. When the disease is moderate or severe and is definitely associated with a specific type of pneumococcus, comparatively small doses of the homologous antibody given after a few hours of drug therapy will frequently bring about rapid clinical improvement, making it possible to dispense with further drug therapy much sooner.

It appears from the analysis of the clinical data that specific antipneumococcus serums and sulfapyridine are both highly effective agents in the treatment of the pneumococcal pneumonias in adults and that, in the great majority of cases, they are probably equally effective. It is natural, under such circumstances, that the physician will choose sulfapyridine for the treatment of most of his cases since, in general, it is simpler to administer, is more widely effective and is less expensive than are the serums. The more detailed analysis of the results of treatment in various groups of cases indicated certain situations in which the combination of serum and sulfapyridine gave better results than did either agent alone. In general, these represent the cases with the worst prognosis and warrant the use of the combined therapy.

In any given case it may become desirable or necessary to give specific serums because the patient falls into one of the categories in which the combined therapy is most effective, because the toxic effects of the drug may interfere with its effective use or occasion undue discomfort, or because the infection may prove resistant to the action of the drug. The physician should therefore be prepared for this contingency by obtaining sputum for typing and blood for culture as soon as the clinical diagnosis of pneumonia is made or suspected. Sulfapyridine therapy may then be started before the results of these procedures become available, unless there is some reason for withholding the drug. If the patient falls into one of the groups

of severe cases, or is one in whom sulfapyridine therapy is considered undesirable, serum should be given as soon as the type is determined or the result of the blood culture becomes known. The immediate use of sulfapyridine makes possible a period of observation during which doubts concerning the severity of the infection can be resolved and evaluated, particularly while the results of the blood culture are being awaited. In any patient, serum may be used to advantage if twenty-four to thirty-six hours of drug therapy fails to bring about marked clinical improvement.

CONCLUSIONS

Both specific antipneumococcus serums and sulfapyridine are highly effective agents in the treatment of the pneumococcal pneumonias.

The results of laboratory studies suggest that the combination of serum and sulfapyridine represents the optimum therapy in pneumococcal infections.

An analysis of the clinical results of treatment with serum and sulfapyridine, used separately and in combination in adults with pneumococcal pneumonia, indicates that for the large majority of cases each of these two agents is about equally effective when used alone, and that for most of the cases with the worst prognosis the combination of serum and sulfapyridine is more effective than is either agent alone.

The cases in which the combined therapy was most effective included the following bacteremic patients, particularly those over fifty years of age, those in whom treatment was started late in the disease and the ones with blood cultures that yielded moderate or large numbers of pneumococci, patients in whom more than one lobe was involved, most patients over sixty years of age who had more than a mild infection, and pneumonias due to Types 2, 3 and possibly 5 pneumococci except the mild cases.

Since sulfapyridine has a wide range of effectiveness, is usually simple to administer and is relatively inexpensive, it is advisable to start treatment with this drug in every case of pneumonia as soon as the clinical diagnosis has been made, but only after blood has been taken for culture and every effort has been made to obtain sputum for typing. In the severe cases that fall into the categories enumerated, — and to these may be added

the pneumonias complicating pregnancy and the puerperium, — specific serum should be given as soon as the causative types have been determined or the results of the blood cultures have become known. In addition, patients in whom continued drug therapy may prove harmful are best treated with serum as soon as the type is known. They include patients with renal or hepatic disease and those with severe anemias or other blood dyscrasias. The establishment of a balance of antibodies will permit early withdrawal of the drug and thus minimize its ill effects.

In all other cases due to specific types of pneumococci serum should be used if there is no satisfactory response after twenty-four to thirty-six hours of drug therapy.

In cases treated early in the disease, serum may be preferred, particularly where the drug is not well tolerated because of the dramatic response so regularly obtained with comparatively small doses of serum and because prolonged therapy may be necessary to avoid relapse of the infection when the drug is used alone.

this clinical finding is coupled with the experimental work, particularly that of Lanman and Ingalls,¹⁹ the possible inference is obvious in surgical patients the vitamin C is withdrawn from the blood postoperatively in order to be utilized in the process of wound healing. And if this inference is coupled with the belief that a plasma level of ascorbic acid of below 0.5 mg per 100 cc in adults is dangerously low, the conclusion must be that anyone with a vitamin C level below this figure is apt to have poor wound healing or dehiscence, even in the absence of other complicating factors. Such an inference would seem to conflict with the facts, since, before any great attention had been focused on vitamin C, the incidence of poor wound healing in a large series of abdominal cases dropped from 4.3 to 1.2 per cent when care was taken to use modern methods of suturing and to exercise gentleness in handling the tissues.²² Moreover, Lund²¹ has reported a large group of patients with known low plasma vitamin C levels who nevertheless showed perfectly normal wound healing. These findings do not support the suggestion that high plasma vitamin C levels are essential to proper wound healing in the average surgical patient. Do multiple avitaminoses, growth factors and infections play a role in the frequent cases of clinical and subclinical scurvy and its complications reported in the literature? Are these factors partly responsible for the widespread belief that plasma levels of ascorbic acid below 0.5 mg per 100 cc are dangerously low? Are plasma levels of ascorbic acid a good index of the vitamin C status of the adult? These questions led to the following experiment.

J. H. C., a normal 27-year-old man, weighing 158 pounds, with negative history, physical examination and laboratory findings, placed himself on a vitamin C-free diet supplemented by vitamins A, B, D, G and later E. During the entire experiment he remained active, carrying out his assigned duties as assistant resident surgeon in a large general hospital.

For the first 2 months the diet consisted of well-cooked meat, not over 200 gm per day, bread, butter (not over 30 gm. per day), cake (containing no fruit or fruit flavoring), corn flakes, polished rice and coffee, small amounts of cream (not over 30 cc. per day) being allowed for coffee and cereal. For the next 6 weeks the diet consisted of Swiss and American cheese (not over 240 gm per day), crackers, black coffee, beer (not over 1500 cc. per week) and a semi-sweet chocolate candy bar, a standard brand which, according to the makers, consists only of chocolate bean, roasted and then processed at 200°F for 72 hours, and sugar. This latter diet was thereafter supplemented with 2 eggs per day. There was no deviation from the dietary regimen at any time.

Daily plasma vitamin C determinations were done by the macro-method of Mindlin and Butler¹⁰ using the Evelyn photoelectric colorimeter,²³ with correction for turbidity as suggested by Bessey.⁸ At first the samples of blood were collected in cyanide according to the method

of Pijoan and Klemperer,¹¹ but this method was later discarded, oxalate alone being used. Determinations were always made as soon as the blood had been withdrawn. During the entire period, frequent control determinations were made. The results of all determinations are represented in Figure 1.

During the entire dietary period frequent capillary fragility tests, according to the technic described by Göthlin,² and other laboratory procedures (*vide infra*) were carried out.

After 85 days of vitamin C-free diet, and after the plasma vitamin C had been zero for at least 44 days, an experimental wound consisting of a 6-cm transverse incision was made in the right midback, being carried down

FIGURE 2 Biopsy Specimen from Subject

through the latissimus dorsi muscle and the anterior spinalis fascia. Several small bleeders were ligated with plain No. 00 catgut. Approximately 2 gm. of the spinalis muscle was removed for analysis, the deep fascia being then closed with interrupted plain No. 00 catgut sutures, a few of the same being placed also in the superficial fascia. The skin was closed with multiple interrupted silk sutures. A wound of similar proportions was made simultaneously in a normal adult male control whose plasma ascorbic acid levels had been high, and who remained on a diet high in vitamin C throughout the experiment. Twenty-four hours preoperatively the control was given 200 mg of ascorbic acid by mouth, and a plasma determination was done 30 minutes later. The result

high value may partially account for the sharp postoperative drop apparent in the chart.

The biopsied specimens of sacrospinalis muscle were analyzed by Dr O. A. Bessey of the Harvard Medical School, who could find no vitamin C in the muscle of the subject, although there was an appreciable amount in that of the control. Although the possibility exists that some of the ascorbic acid present in the former specimen was oxidized by small amounts of blood present, Bessey considered the difference between the two samples significant since this factor of oxidation was present in each.

The activities of neither the subject nor the control were

FIGURE 3 Biopsy Specimen from Subject.

restricted postoperatively and their courses were uneventful except for a slight elevation of temperature on the 1st day (subject, 99.6 F control 99.4 F). On the 6th postoperative day the sutures were removed both wounds being clean. On the 11th postoperative day sizable specimens were taken from the wounds of both the subject and the control, the incision being carried down to the extreme depth of the previous one and transversely to it. Sections of these specimens showed no appreciable difference between the granulations of the subject and of the control. Not only excellent proliferation of fibroblasts but also ample intercellular substance and capillary formation could be seen in the granulation tissue of the vitamin C deficient subject. Healing of the wounds was uneventful in each case.

DISCUSSION

Inspection of the chart will reveal that the plasma ascorbic acid concentration fell rather rapidly during the first eleven days of the diet, and then remained between 0.14 and 0.0 mg per 100 cc. for approximately twenty-eight days. Thereafter the values remained so close to 0.0 mg that they may be considered as such, particularly since they check with those determined at the Children's Hospital.

Butler and Cushman,²⁰ who believe the ascorbic acid levels in the white cells and platelets to be a much better index of vitamin C deficiency than are the plasma levels, made such analyses for us by a technic recently developed in their laboratory, and found a gradual drop in the vitamin C level in the white-cell layer of centrifuged blood from 28.0 mg per 100 cc. on the seventeenth day to 4.0 mg on the eighty-second day and to 0.0 mg by the one hundred and twenty-second day of the diet (Fig 1). According to Butler and Cushman the values of 4 to 0 mg per 100 cc in the white cells and platelets are comparable with those found in scorbutic infants, the average normal level being 34 mg.

It is interesting that during the period of the experiment no sign or symptoms of scurvy developed. The lack of appreciable difference in the wound healing of the subject and of the control and the abundance of intercellular substance in the biopsied specimen of the deficient subject are consistent with these negative clinical findings. Also worthy of consideration, however, is the fact that no vitamin C was detected in the biopsied muscle of the deficient subject. This finding, in view of the ample intercellular substance in the healing wound, may be of importance, since some recent investigators,²¹ repeating the work of Wolbach and Howe,¹² have been unable to confirm the finding of lack of intercellular substance in scorbutic guinea pigs.

During the dietary period there was a moderate weight loss (18 pounds).

It will be seen on inspection of Figure 1 that the basal metabolic rate fell to -20 per cent between the sixty-ninth and eighty-second days of the diet, during which time the subject was on an intake of cheese and crackers and was losing weight. Since higher values were later obtained, we now believe these low metabolic rates were the result of inanition or diminished specific dynamic action of ingested protein or both.

A slight fall in the red-cell count and the hemoglobin, reaching a minimum around the beginning of the third month of diet, was rapidly corrected by the intake of 8 gr of ferrous sulfate daily, so that within two weeks the red-cell count had re-

turned to 5,000,000 and the hemoglobin to 97 per cent (determinations done at the Thorndike Memorial Laboratory) This is of some interest in view of the fact that the subject lost approximately 2300 cc of blood in total volume of specimens taken and two transfusions given during the experimental period

All other laboratory work—including the examination of stools and urine for blood and of blood smears, differential leukocyte counts, the determination of hematocrits, mean corpuscular volumes, hemoglobins, bleeding and clotting times, sedimentation rates, blood-complement, blood sodium, blood cholesterol, blood lipid, serum protein and albumin-globulin ratios, fasting blood sugar and sugar-tolerance tests, capillary fragility tests, chest x-rays and electrocardiograms—remained essentially normal

There was no increased fatigue on muscular exertion as measured by tests on an ergograph although subjectively there was a mild lassitude The gums remained in good condition

SUMMARY

A normal active adult placed himself on a vitamin-C-free diet supplemented by the other known vitamins Over a period of four months, during which the ascorbic acid content of the plasma, white cells and platelets fell to zero, no signs or symptoms of scurvy developed An experimental wound made after twelve weeks of the diet, when the plasma readings had been zero for at least forty-four days, showed good healing both grossly and microscopically when a biopsy specimen was taken eleven days later No lack of intercellular substance could be seen Analysis of the muscle removed showed no trace of ascorbic acid Except for the aforementioned changes in vitamin C concentrations, extensive clinical studies revealed only a transient fall in hemoglobin (reversed by iron) and a fall in basal metabolic rate and body weight

It is, of course, to be remembered that only a single case is reported, so that no positive conclusions can be reached We believe, however, that this study suggests the following

In the absence of multiple avitaminosis, infection or growth factor, a plasma ascorbic acid of below 0.5 mg per 100 cc. is not necessarily dangerously low

Plasma ascorbic acid levels are a poor index of clinical vitamin C deficiency in the adult. Rather, they probably indicate the degree of saturation, which should not be confused with deficiency

The apparent ascorbic acid content of the circulating white cells and platelets may fall to zero without the appearance of clinical scurvy in an adult on an adequate intake of vitamins other than vitamin C

END RESULTS IN THE INJECTION TREATMENT OF
INGUINAL HERNIA*

HORACE K. SOWLES, M.D.,† AND WILLIAM M. SHEDDEN, M.D.‡

BOSTON

ABOUT three years ago there was considerable agitation throughout the country in regard to the injection treatment of inguinal hernia. The subject was widely discussed in the literature. One group of surgeons declared that here was a panacea with the aid of which one could obtain as high as 94 per cent of cures. This was in sharp contrast to the opinion of a more pessimistic group who stated that this procedure was of little or no value and that hernias so treated recurred in over 80 per cent of cases. As a result of this great divergence of opinion, we believed that we should make a clinical study in an attempt to evaluate this type of treatment. The chief fact that we wished to discover was the true percentage of recurrences after injection treatment. This study necessarily could not be completed in less than two or three years, because the figures would be of no value unless the end results were at least a year old.

At the beginning of our study the criteria for the acceptance of a case for treatment were rather broad, but as time went on we found that we were definitely limiting the group which we considered suitable. On the other hand, we accepted a considerable number of patients who were poor operative risks or gave poor prospects for cure under any form of treatment. We of course excluded patients with strangulated or incarcerated hernias, postoperative hernias and hernias that could not be completely reduced and properly held with a truss, as well as all patients with a general systemic disease that might contraindicate this type of treatment.

The objectives to be obtained in the cure of an inguinal hernia are the same whether treatment consists of surgery or of injection. These objectives are the obliteration of the sac and the sealing of the inguinal canal. Obviously the number of injections necessary must be discovered by trial and error. During the course of our study we found that the number given to any one individual was comparatively high. There is no question that the patient must be treated vigorously in the early stages. Early disappearance of the impulse in the inguinal canal and the firmness of

the muscles give false assurance, and the injections must be continued even after such conditions obtain, because there is sure to be a certain amount of subsequent relaxation as the inflammatory process subsides. We believe that the minimum number of injections should be twelve, and some of our cases received as many as eighteen or twenty.

The cases that we accepted as suitable and that were treated by the injection method were those of indirect inguinal hernia in which the sac did not exceed 4 cm in diameter and the external ring did not exceed 2 cm in diameter. We realize that the distinction between direct and indirect inguinal hernias cannot always be made with accuracy, but the correct diagnosis can be determined in the majority of cases. Undoubtedly we have included without knowing it a certain number of direct hernias, and this probably accounts for a certain number of recurrences, a fact which was, indeed, proved by operation in several cases. The inclusion of such hernias has made our end results appear worse than they really were, and the figures are therefore conservative. We have found obesity to be a definite contraindication because fat people are almost sure to develop recurrences.

We shall not discuss anatomy, histology or technic because these phases of the question have been amply covered by others writers. It is sufficient to say that for the purpose of this study we used the injection technic described by Rice,* and to simplify the study we used the same injection fluid on all cases (a 5 per cent solution of sodium psyllate put out under the trade name of Slynasol). The reason for selecting this solution was that it is relatively mild in action, can be given in doses of 3 cc. or more and does not have to be preceded by a local anesthetic. Not only did the absence of the local anesthetic simplify the technic, but also pain was an indication that the point of the needle was about to penetrate the peritoneal cavity.

Most patients made no complaint of pain following the injection but described only a sensation of soreness lasting from twenty four to forty-eight hours. One patient refused further treatment after three injections, on the ground that the pain was unbearable for two or three days after each injection. One patient was hospitalized because of sudden pain twelve hours after the fifth injection.

Rice, C. O. The injection treatment of hernia: an evaluation of the technic and results. *Ann. Surg.* 105:343-351 1937.

*Read by title at the annual meeting of the New England Surgical Society, Boston, Massachusetts, September 22-30, 1939.
From the surgical services of the Massachusetts General Hospital.

†Assistant visiting surgeon, Massachusetts General Hospital.
‡Assistant in anatomy Harvard Medical School; instructor in surgery, Tufts College Medical School; assistant in surgery, Massachusetts General Hospital.

He was admitted to the Emergency Ward with swelling and pain at the external ring, and was operated on under the mistaken diagnosis of strangulated hernia. The neck of the sac was completely obliterated and the canal was well sealed. The swelling and pain had been caused by an acute hydrocele of the cord, which presumably would have subsided if the operation had not been performed.

During the period of study we saw nearly all the patients with hernias who came to the Out Patient Department. We accepted about half these cases as suitable for injection treatment, and followed them, some as long as three years, for possible recurrence.

The question of recurrence is not always a simple one. We have classified as such any bulging subsequent to a course of treatment. It must be realized that this is an arbitrary definition, since there is no set time when treatment can be said to have been completed. The fact that a patient usually does not have a recurrence while still under treatment may explain the surprisingly small number of recurrences reported by some writers. For instance some patients developed a small recurrence several months after completing a course of injections, but were permanently cured after receiving a few more treatments. It has become increasingly clear that both the patient and the doctor must persist with the treatment, and that, if so, an increasingly higher percentage of cures will result, though we realize that the prolongation of treatment is one of the objections to this method. It is interesting that some of the patients were cured by less than twelve treatments. One remained cured for one and a half years after ten injections, another for two and a half years after eleven injections, and a third for two years after only six injections.

As regards the complications with this form of treatment, a few patients had mild pain for several hours, and a few had some swelling of the cord, in most cases painless. Rarely did we see a mild syncope that passed off within fifteen or twenty minutes. We have no knowledge of any nerve injury, sterility or impotence as a result of the treatment. We routinely examined the testicles before starting treatment, and noticed no atrophy after it had been completed. An occasional small hematoma occurred which required no treatment. Blood appeared in the syringe on a few occasions. The needle was promptly withdrawn and the injection was continued in a new location. In a few cases an annoying dermatitis developed from irritation caused by the truss, and 1 patient had to give up the treatment altogether because a severe dermatitis occurred whenever it was worn.

We found that the hernias recurring after injection

were much smaller than the original ones, and possibly we should have given further injections in these cases. In most cases we did not do so, but resorted to surgery, not wishing to subject the patient to the time and trouble of a new series of injections.

A number of those given palliative treatment were made much more comfortable, and although there was no hope of discarding the truss in some of these cases, it held the hernia much more effectively and comfortably after the injections. We believe that this method of treatment has a definite prophylactic value which must be considered in its evaluation.

Patients with potential hernias can certainly be benefited. Several patients applied to us for injections who had no real hernia but were kept from obtaining employment because of relaxed or enlarged rings. A few injections gave these patients complete relief.

Of 109 cases followed up, 32 (29 per cent) had recurrences. The longest time any patient was observed to remain cured was forty-two months, and the shortest two months, the average period being fourteen months. The elapsed time without recurrence since the last treatment was from a year to a year and a half in 68 cases, from a year and a half to two years in 38 cases and over two years in 19 cases.

The advantages of injection treatment are as follows: it is safe, the mortality rate being zero, there are no serious complications, and even the minor complications, such as pain, the puncturing of a blood vessel, induration of the cord and peritoneal irritation, are not serious, the patient remains ambulatory during the course of treatment, and does not suffer loss of time or pay or the expense of hospitalization. The chief disadvantages of the method are that it is prolonged, and that the recurrence rate is higher than one would expect following expert surgery.

CONCLUSIONS

We do not believe that the injection method is a cure-all for hernias, or that the physician should apply it to every hernia that he encounters. The selection of suitable cases is not easy, but as a result of our experience in this series we can now select them with greater accuracy, and under these conditions should be able to hold the recurrence rate to 25 per cent. In general the ideal patient is active, has good musculature, is not obese and has an indirect inguinal hernia of small or moderate size.

The technic of injection is exacting, and one must be able to visualize in detail the anatomy of the inguinal canal if the procedure is to be successfully carried out.

GRANULOCYTOPENIA FOLLOWING BARBITURATE THERAPY

Report of a Case

ARTHUR J. HADLER, M.D.*

BOSTON

FEW cases of granulocytopenia due to medication with the barbiturates have been reported. The following case is presented as an example.

CASE REPORT

M. L. M., a 30-year-old, unmarried woman was admitted to the Long Island Hospital April 28 1939. Except for an occasional attack of asthmatic bronchitis, she had been well until 5 days previous to admission, when she developed a sore throat, a nonproductive cough, fever, malaise, hoarseness and vomiting.

Physical examination showed reddening of the mucous membrane of the pharynx, palpable cervical nodes, hoarseness, and sibilant and sonorous rales throughout the chest. The white-cell count was 6500. The temperature which was 102 F. on admission fell promptly to 99 or 100. On May 5 the chest was clear and resonant, and the patient was asymptomatic save for a slight cough. During this period she had received glucose gargles, acetylsalicylic acid, ephedrine sulfate, syrup of hydriodic acid and ammonium chloride. An x-ray film of the chest showed no abnormality. The sputum was negative for tubercle bacilli. Urinalysis was essentially negative. A blood Wassermann test was negative.

On May 4 for insomnia the patient was given 1½ gr. pentobarbital sodium, but because of depression the next day it was discontinued. On May 5 one tablet of Allonal was given. Three hours later after a shivering chill the temperature was 102 F. The patient felt wretched, had a headache and could not sleep. On May 6 she was given 3 gr. Sodium Amytal and had a sound sleep without a "hangover." On May 7, 8 and 9 she received an Allonal tablet each night but did not sleep well. Because of pain over the left maxillary sinus a history of sinusitis and a persistent fever of 99 to 100 F., x-ray films of the sinuses were taken on May 9. They showed thickened membranes in both antrums but no fluid level. The patient was discharged May 11 with a normal temperature.

She felt well until May 19 when pain began in both submaxillary regions. Insomnia, headache, weakness and lassitude became marked. She took several aspirin tablets and two Allonal tablets on May 20. On May 21 she took more aspirin and another Allonal tablet. On May 22 at 1 a.m. her temperature was 101 F. and at 3.30 a.m. 103.4 after a shivering chill for 1 hour. She was readmitted to the hospital where examination showed only tender submaxillary nodes. The hemoglobin was 95 per cent, the red-cell count 4,500,000 and the white-cell count 1050 with 4 per cent neutrophils (band forms) 8 per cent myelocytes 80 per cent lymphocytes, 4 per cent monocytes and 4 per cent eosinophils. A few hours later the white-cell count was 2250 with a similar differential count. Table 1 shows the counts as they rose thereafter. Therapy consisted only of 0.5 cc. of Reucologen, a concentrated liver extract, administered intramuscularly once daily. The fever rapidly subsided. Coincident with an upper-respiratory infection there was a fall in the leukocyte and neutrophil counts after the original rise to normal, but recovery was spontaneous, since liver therapy

had been discontinued when the counts first reached normal.

The patient stated at this time that in 1936 following extraction of a tooth under novocain anesthesia, she had had local pain, adenopathy, sore throat, exhaustion and a fever of 101 F. and that she had been given some unidentified tablets. A low white-cell count, which she believed was 1200 was found. Other counts were taken and she was confined to a hospital, the records of which stated that her dentist had found a white-cell count of 3500 of which only 10 per cent were polymorphonuclears (band forms). Later blood studies at that hospital showed a hemoglobin of 81 per cent, a red-cell count of 4,620,000 and a white-cell count of 3000 with 16 per cent neutrophils (5 per cent band forms) 30 per cent lymphocytes 52 per cent monocytes and 2 per cent basophils. The temperature dropped rapidly to normal, and the patient was discharged with the diagnosis of mild agranulocytosis.

On the second admission to the Long Island Hospital the patient complained of pain at the angle of the right jaw from a known infected and impacted wisdom tooth. An x-ray film showed no abscess formation. On June 7 she was given 10 cc. of 1 per cent novocain subcutaneously to test for sensitivity. Since there was no change in the blood counts, on June 8 the tooth was extracted under novocain anesthesia. Following this there was a leukocytosis for about a week. The patient was discharged June 15.

After discharge frequent blood-cell counts were taken. These appear in Table 1. On July 5, patch tests were done with acetylsalicylic acid and acetphenetidin. Allonal and barbitals all were negative. Tests were then begun in order to determine whether a drug had caused the granulocytopenia. Allonal was suspected. On July 12, 13 and 14 doses of 5 gr. of acetylsalicylic acid were taken each day with no resultant leukopenia or neutropenia. On July 17, 18 and 20 doses of 5 gr. of acetphenetidin were taken each day with no subsequent leukopenia or neutropenia. On July 24 at bedtime, an Allonal tablet was taken. The next day both the white-cell count and the percentage of neutrophils had risen (7750 with 93 per cent neutrophils). The patient felt marked lassitude, weakness and slight dizziness. The following night she took another Allonal tablet. The next day she was near prostration and had to remain in bed most of the day. The white-cell count was 4350 with 51 per cent neutrophils. In 2 days the count had risen and she felt fairly well again. Since Allonal had produced this effect and since acetphenetidin had produced no effect, the alurate component seemed responsible. Alurate was not available, but sodium alurate was obtained in 3½ gr. capsules (equivalent to approximately 3 gr. of alurate). On August 1 the patient was given a third of the contents of one of these capsules on retiring. The next day the white-cell count was 5800 with 70 per cent neutrophils. The following night she took a similar quantity of sodium alurate, and the next day the white-cell count was 2800 with 63 per cent neutrophils. After the first dose of sodium alurate there was considerable lassitude and weakness after the second dose the pa-

*Senior assistant resident, Long Island Hospital, Boston.

†Since January 1939 Allonal has been composed of alurate (1 gr.) and of acetphenetidin (3 gr.)

patient was prostrated. The white-cell count fell to 1800, with no neutrophils (Table 1). She remained weak and devoid of energy, the gums became sore, the submaxillary regions ached and the temperature gradually rose to 102°F on August 7. That night she had cold chills and sweats

was given 1 cc of Reticulogen intramuscularly, and later 10 cc of Pentnucleotide intramuscularly in the buttock. Within 1 minute after the Pentnucleotide injection she noticed dryness of the throat, asthma set in with labored breathing and wheezing, and there was marked numbness

TABLE 1 Summary of Data

| DATE (USUALLY AT 11 A.M.) | WHITE CELL COUNT | NEUTRO- PHILS % | LYMPHO- CYTES % | MONO- CYTES % | EOSINO- PHILS % | BASO- PHILS % | MYELO- CYTES % | REMARKS |

The right tonsillar region became sore, and two spots of exudate appeared there. There was anorexia, and severe headache.

On August 7 the patient received 1 cc. of Reticulogen intramuscularly. On August 8 the patient vomited, the cold chills continued and she was again hospitalized. She

down the inside of each arm and in the fourth and fifth fingers of each hand. The patient felt as though she were dying, the sensation beginning at the fingers and working upward. There was no substernal pain or constriction. One cubic centimeter of adrenalin gave prompt relief. Following this, two injections of 5 cc. of Pentnucleotide with

0.5 cc. of epinephrine and 1 cc. of Reticulogen were given daily. The Pentuonolone produced mild transitory numbness of the fourth and fifth fingers. The white-cell counts steadily rose under this regime. The percentage of eosinophils rose to 30, suggesting an allergic reaction. During all stages of the illness, but especially during recovery the patient showed many band forms and myelocytes, except during the extreme neutropenia. She always had a large number of platelets, many of them being very large. The red cells were essentially normal.

The patient made an uneventful recovery and was discharged August 13. It had been hoped that the effect of Pentobarbital-Sodium could be determined by the test-dose method also, since it had a "hangover" much like that caused by Allonal and sodium alurate, but it was deemed best not to risk the repeated production of granulocytopenia, and it was decided to avoid barbiturates in this case in the future.

This case is reported as one of granulocytopenia due to a barbiturate, alurate (allylisopropylbarbituric acid). Proved cases of agranulocytosis due to the barbiturates, especially those not containing a benzene ring, are quite rare. In 1933 Watkins⁸ reported without details 32 cases of agranulocytosis, of which 12 seemed due to barbiturates. One patient who had taken amidopyrine several times with resultant agranulocytosis developed granulocytopenia on another occasion after four daily 1½-gr doses of Pentobarbital-Sodium (sodium ethyl [1-methyl-butyl] barbiturate). Four other patients who took this drug died of agranulocytosis in their first attack. Five patients who took Amytal (isomylethylbarbituric acid) or its sodium salt preceding their neutropenia died, 4 in the first attack and 1 in the third. One patient died of agranulocytosis after taking phenobarbital (phenyl ethylbarbituric acid), but severe sepsis was also present. A patient who developed a toxic rash and leukopenia after taking phenobarbital recovered. Watkins did not believe that his cases proved that amidopyrine or the barbiturates were the etiologic factor in the agranulocytosis, but suggested that the patients might have had an idiosyncrasy, manifested by agranulocytosis. Hardwick and Randall⁹ found no agranulocytosis in 59 obstetric cases under pentobarbital-sodium analgesia, and Teel and Reid¹⁰ found none in 3592 cases in which this drug was used. The Council of Pharmacy and Chemistry of the American Medical Association¹¹ in 1934 stated "No definite case [of granulocytopenia] has been reported in which a barbiturate alone is responsible. From the present data it appears that barbiturates have little or nothing to do with granulocytopenia. Kracke¹² in 1934 agreed with Hardwick and Randall with regard to pentobarbital, and declared that he had made similar observations relative to all types of the so-called barbiturates. He emphasized that in no cases had the barbiturates alone ever been suspected of an

etiologic role in this disease, except possibly by Watkins. Kracke believed that drugs with a benzene ring, particularly those with an attached amine group, most often caused granulocytopenia. Bolton¹³ in 1935 concluded that the barbiturates, having two $-NH$ radicals, should be theoretically more toxic than amidopyrine, but stated that on the contrary the prevalence of barbiturate medication as a hypothetical factor in the etiology of the disease is relatively slight in comparison with that of amidopyrine. Madison and Squier¹⁴ and Benjamin and Biederman¹⁵ were unable to cause granulocytopenia with barbiturates in patients after recuperation from agranulocytosis due to amidopyrine. Meyer¹⁶ in 1936, reporting a series of 14 cases of agranulocytosis, mentioned that in 3 the only drugs taken beforehand were barbiturates (barbital, Sodium Amytal and "drugs of the barbiturate group"), but no causal relation was implied. Jacobson¹⁷ in 1938 reported a case of neutropenia following five years use of phenobarbital, but there was marked anemia also, so that this was not a pure case of agranulocytosis. Some cases listed in the *Quarterly Cumulative Index Medicus* as agranulocytosis following the giving of Amytal are found to be cases following the administration of Amytal Compound, a preparation containing amidopyrine. From the literature available, therefore, it appears that proved cases of granulocytopenia due to the barbiturates, especially those with no benzene ring, are distinctly infrequent.

About 300 cases of granulocytopenia following the administration of amidopyrine and proprietary drugs containing it have been reported. In the latter group Allonal formerly belonged, but, as previously mentioned since January, 1939, the formula has been changed from a combination of amidopyrine and alurate to one of acetphenetidin and alurate. No cases due to the "new Allonal, which this patient received, have been reported. Acetphenetidin has been suspected on three occasions as the causative factor in agranulocytosis. Kracke¹¹ in 1931 reported a case of fulminant agranulocytosis in a person who had taken large doses of acetphenetidin. This patient had marked methemoglobinemia over a long period and had been treated with many vaccines, three times for typhoid immunization, at first the case had been reported as one of agranulocytosis following typhoid vaccination. Costen¹⁸ in 1933 cited a case of agranulocytosis in which the patient had taken large doses of aspirin, phenacetin and bromides. Kracke and Parker¹⁹ in 1934 reported another case following acetphenetidin. With these exceptions acetphenetidin has not been blamed for the causation of granulocytopenia. The patient herewith reported had been given three daily doses of 5 gr. of acet

phenetidin (only 3 gr of acetphenetidin are contained in each Allonal tablet) with no effect on the blood, whereas two 1-gr doses of sodium alurate caused granulocytopenia. Hence, the alurate fraction rather than the acetphenetidin in the "new" Allonal appears to have been the etiologic agent causing granulocytopenia.

According to Jackson and Merrill¹⁴ and Thompson,¹⁵ 80 per cent of the patients with agranulocytosis are women, and a remarkably large number of attacks of granulocytopenia occur at or about the time of the catamenia. In Thompson's cases when recurrences took place, each coincided with the onset of the menses. Two of his patients who had previously had agranulocytosis showed distinct but transient asymptomatic neutropenia just before the onset of menstruation. This patient had a menstrual period from June 15 to 18 during the leukocytosis following tooth extraction, another from July 8 to 11 without any variation in the leukocyte or neutrophil count, and still another from August 3 to 6 during the last bout of neutropenia after sodium alurate. The catamenia had occurred just before the first admission for neutropenia on May 22, but Allonal medication had been taken before this neutropenia. From July 8 to 11 there had been no medication and the catamenia had no effect on the blood counts, giving a control period under observation. Incidentally it may be mentioned that the blood counts were almost all taken at the same time of the day, in order to eliminate error due to the normal diurnal variation in the white-cell count.

Patch tests were negative, but this has been reported in similar cases. Dameshek and Colmes¹⁶ reported 4 cases in all of which scratch, intradermal and patch tests were negative with amidopyrine, the offending drug. Fitzhugh¹⁷ states that the ordinary cutaneous tests for sensitivity to drugs are of little value in the case of hematologic sensitivity, whether negative or positive. He advocates the test-dose method, such as was used on this patient.

With respect to the relation of tooth extraction or sinusitis to agranulocytosis, it may be mentioned that Hill¹⁸ in 1926 reported 2 cases of agranulocytosis, 1 fatal, following extraction of teeth, without post-extraction medication, and Walsh¹⁹ in 1939 reported a case of agranulocytosis associated with maxillary sinusitis. The reported patient, however, had had medication after her tooth extraction in 1936, leukocytosis followed tooth extraction in June, 1939, the last bout of granulocytopenia had no relation to tooth extraction, and the sinusitis was neither acute nor marked, so that tooth extraction and sinusitis probably were not of etiologic significance in the granulocytopenia.

An interesting point for consideration is the similarity of structure of alurate (allylisopropylbarbituric acid or allylisopropylmalonyl urea) and Sedormid (allylisopropylacetyl carbamide or allylisopropylacetyl urea) and of their hematologic effects. McGovern and Wright²⁰ in 1939 stated that 45 cases of thrombocytopenic purpura hemorrhagica had been due to Sedormid. Kracke²¹ in 1938 noted that Sedormid had not been reported as a cause of agranulocytosis. Moody²² reported a case of purpura following Sedormid in which the neutrophil count dropped to 42 per cent with a white cell count of 7500, McGovern and Wright one in which the leukocyte count fell to 3350 with 36 per cent neutrophils, and Huber²³ one in which the leukocyte count dropped to 3350 (differential count not given). Apparently Sedormid, the structure of which is quite similar to that of alurate, can depress the leukocytes, particularly the granulocytes, as well as the platelets.

Fitzhugh¹⁷ in 1938 described abnormal leukocytosis after amidopyrine and other drugs. This seems to have happened after the first test dose of Allonal (7750 leukocytes with 93 per cent neutrophils) before leukopenia set in, as though marrow stimulation preceded depression. Fitzhugh also believes that the presence of young cells with granulocytopenia indicates "primary arrest of maturation" of the leukocytes, a "pernicious leucopenia" analogous to pernicious anemia, except that the leukocytes are arrested in their maturation process. The reported case showed immature neutrophils during most of the granulocytopenic period. Whether the liver extract or Pentnucleotide speeded up the maturation process is uncertain, for at least twice, in 1936 and in June, 1939, she recovered spontaneously, but it is true that convalescence followed rapidly after treatment was initiated.

SUMMARY

A case of granulocytopenia due to the "new" Allonal (alurate), with recovery following liver extract and Pentnucleotide therapy, is described and discussed.

The few reported cases believed due to barbiturates are mentioned.

The similarity of alurate and Sedormid in structure and in hematologic effect is noted.

CLINICAL NOTE

DEVICE FOR ENSURING CONSTANT GASTRIC SUCTION*

ROBERT S. HORMELL, M.D.†

BOSTON

THE water suction siphonage method of Wangenstein§ is widely used for the decompression of the upper gastrointestinal tract. The device described here adapts the suction offered by a hospital vacuum system to the Wangenstein principle.

The source of suction may be a hospital vacuum system piped to the bedside or a motor suction machine which is to be found in many hospitals (Fig. 1). An airtight trap (A) should be interposed between the source of suction and the water column to prevent damage to the suction system. The jacket of the water column (B) is a 25-cm glass tube, 150 cm. long. Five millimeter glass tubes (C) are thrust through rubber stoppers at either end, these should extend to within 5 cm of the opposite end of the outside tube. Their inner ends are drawn out to the fineness of a medicine dropper to diminish the size of air bubbles. At the dependent end of the water column a short glass tube (D) is thrust through the rubber stopper, a rubber tube with clamp attached to this serves to drain off the water. A T-tube (E) is attached to the lower end of the apparatus and tubes from the

house vacuum and the patient are attached. A trap (F) to catch gastric fluids completes the circuit.

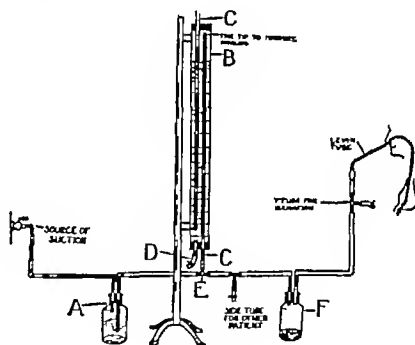

FIGURE 1

In the standard Wangenstein method a suction pressure equivalent to 75 cm of water is maintained, but the degree of suction may be varied at will by changing the height of the water column.

This method offers the advantages that the suction is continuous, nursing care is limited to emptying and measuring the contents of the trap and the amount of gastric fluid removed can be simply determined. It has been successfully used on approximately 30 ward cases over a period of three months.

REPORT ON MEDICAL PROGRESS

THE DIAGNOSIS AND TREATMENT OF NUTRITIONAL DEFICIENCY*

ARNOLD P. MEIKLEJOHN, B.M. (OXON)†

BOSTON

THE advent of purified and synthetic vitamins has created a considerable impression on both medical and lay opinion. The layman, perceiving the partial truth of the proverb that a man is what he eats, has been eager to accept the value of vitamins. The physician, provided with a new therapeutic weapon, and one furthermore that is apparently devoid of danger, has been equally glad to make use of this new achievement of biochemical science. The result has been that the literature is now replete with reports of the value of vitamin therapy in a remarkable variety of clinical conditions. Unfortunately many of these reports are based more on enthusiasm than on judgment. Although the administration of additional vitamins has been recommended in a number of conditions in which there is no definite evidence of nutritional disorder, it cannot be said that such recommendations are as yet supported by sufficiently reliable evidence to render them generally acceptable. Up to the present time vitamin therapy has been proved to be of value only in cases presenting positive clinical evidence of deficiency. If this limitation is not kept in mind, it seems likely that present enthusiasm will soon be replaced by disillusionment, resulting in the discrediting of the true value of nutritional therapy.

The purpose of this paper is to summarize the more valuable clinical criteria by which nutritional deficiency can be recognized, with the hope that it may help to define more clearly the various conditions in which adequate nutritional therapy can be expected to achieve results.

In considering a particular case suspected of nutritional deficiency, it is important at the outset to keep in mind certain general principles. It should be remembered that although nutritional disorders are often the result of economic restriction affecting the quantity and quality of the diet, there are nevertheless a great many individuals in whom such disorders occur in spite of satisfactory economic circumstances. The various predisposing conditions which may be responsible in

such cases have been fully discussed elsewhere¹⁻³; they may be summarized as follows:

A restricted or unbalanced diet, which may result from many causes, such as anorexia, food fads, alcoholism and special diets for gastrointestinal disorders, diabetes mellitus or weight reduction.

Defective absorption of food in organic or functional disorders of the gastrointestinal tract, including loss of teeth, achylia gastrica, gastritis, persistent vomiting, pylorospasm, pyloric stenosis, malignant disease, chronic enteritis or colitis, steatorrhea, parasites, biliary obstruction and surgical short circuits of the intestinal tract.

Increased dietary requirements due to rapid growth (especially in infancy), pregnancy, lactation, hard physical labor, prolonged fever, hyperthyroidism, or loss from the body of formed essentials requiring adequate nutrition for their replacement, as in hemorrhage and albuminuria.

Defective utilization occurring especially in diseases of the liver.^{4, 5}

Another principle to be considered is that the primary effect of dietary deficiency is a change in function rather than in structure. In the absence of adequate supplies of the various essential components of the diet, normal metabolism is impaired. Many of the manifestations of deficiency disease are due solely to disordered metabolism, for which the term "metapathy" is suggested.⁶ Structural changes do not usually occur until the deficiency is well advanced, and are then probably a secondary effect of pre-existing metapathic disorder. Moreover, some structural changes when once established are to a large extent irreversible, such as combined system disease and the bony deformities of rickets. It is therefore absolutely essential that the diagnosis be made before such structural changes have occurred, so that treatment may be instituted when likely to be most effective. This implies that the history and symptoms are of relatively more significance than are physical signs in the early diagnosis of nutritional disease.

It is also worth remembering that deficiency of a single dietary factor is very rarely encountered in clinical medicine. A diet deficient in one es-

*From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

†Assistant and Francis Weld Peabody Fellow in Medicine, Harvard Medical School; research fellow, Thorndike Memorial Laboratory, Boston City Hospital.

sential factor is almost inevitably lacking in others. Thus, although the presenting features of a particular case may suggest an outstanding deficiency of one individual factor, careful search will usually reveal evidence that others are lacking. It is now recognized, for instance, that the classic syndromes of pellagra and beriberi are the result of multiple deficiencies. The fact that they can be identified as definite syndromes is probably due to the uniformity of the diet in the communities where they are endemic. In other localities where deficient diets are less uniform, many of the manifestations of these syndromes occur, although usually presenting a more diverse and less characteristic clinical picture.

Since most deficiencies are multiple, adequate treatment requires the administration of a combination of dietary essentials. In some cases, therefore, it is of little more than academic interest to decide whether the lack of one particular factor is responsible for a given clinical manifestation. From a strictly practical standpoint, it does not greatly matter that the exact causation of some of these manifestations is still obscure, or that some have a multiple etiology. Whatever the underlying cause, the treatment remains the same.

In the succeeding paragraphs an outline is given of some of the outstanding features in the history, physical examination and laboratory data which may be of value in establishing a diagnosis of nutritional deficiency. It should be emphasized that the correct diagnosis of nutritional deficiency frequently cannot be made without a full clinical study, and that many of the manifestations of deficiency are not in themselves diagnostic, and are only significant when considered in relation to other relevant findings. In addition to the special features mentioned, attention should of course be paid to all other abnormalities, particularly those providing evidence of any of the predisposing conditions previously listed.

HISTORY

Age and Sex

The age and sex of the patient should be considered, particularly in relation to the incidence of some of the foregoing predisposing conditions. There is a distinct age incidence in some deficiency syndromes, for instance, rickets occurs in infancy, while pellagrous dermatitis is usually seen in adults. Nutritional anemias are commonest in women and children.

Diet

The dietary history is obviously extremely important and at the same time frequently very difficult to elicit. An attempt must be made to assess

the adequacy of the diet in terms of both quantity (calories) and quality (protein of good biologic value, mineral salts and vitamins). It is useful to know whether the diet has been essentially the same over a period of years, or whether it has undergone some recent alteration. In connection with the quality of the diet, it is particularly important to inquire about the intake of the so-called "protective foods,"—meat, dairy products, fruit and fresh vegetables,—on which the supply of essential food factors largely depends. If the diet is devoid of any of these foods it is a point of definite significance. But if the patient states that they are taken occasionally, "now and then" or "when I can afford it," a great deal of further questioning will not help materially to assess exactly how much of these foods are in fact consumed. The difficulty is that even the most intelligent gourmet finds it hard to remember what he ate two days previously. Furthermore, it is difficult to think of food in terms of quantity, the size of "an ordinary steak" is very much a matter of individual opinion. Most physicians would find it hard to give an account of their meals during the previous week with sufficient accuracy to enable a dietitian to determine correctly their caloric consumption, and whether this varied from day to day. The most valuable information about the diet is frequently derived from facts elicited under the next heading.

Economic History

The amount of money which the patient has available for the purchase of food, together with an estimate of his ability to make the best use of it, is often the most valuable single criterion by which the adequacy of the diet may be judged. No hard and fast rule can be laid down as to the minimum sum which will purchase an adequate diet. It obviously varies very greatly in different communities—whether rural or urban, with or without facilities for home production of food and so forth. The evaluation of the adequacy of a given income must depend on a knowledge of local conditions.

Family History

The family history is useful in providing further information about dietary habits, who prepares the food, and how many others in the household there are to be fed, also whether there is evidence of malnutrition in other members of the family. In the case of a married woman, recent or present pregnancy should be considered. Inquiry should also be made concerning the familial incidence of conditions predisposing to nutritional disorders, such as achylia gastrica and diabetes mellitus. In some cases, particularly when addiction to alcohol is suspected, valuable additional information not

volunteered by the patient may be obtained by questioning friends or relatives

Occupational and Social Histories

The occupational and social histories may give information concerning the regularity of meals and facilities for obtaining them. The nature of the occupation, whether sedentary or active, may help to decide the dietary needs

Habits

The use of alcohol is an important consideration in determining the nutritional status.⁷ Alcohol not only affects the appetite, but because it provides calories without accessory food factors its metabolism tends to exhaust the body's reserves of such substances. Furthermore, chronic alcoholic addicts are notoriously careless about eating

General Health

Inquiry should be made as to the patient's sense of well-being and ability to work, whether there is a feeling of lassitude, fatigue or exhaustion. Change in weight is a vital point. Recent illnesses or operations should be considered. Nutritional disorders frequently follow infectious illnesses, perhaps because of the increased nutritional requirements during fever, combined with a diminished intake of food and impaired digestion. This fact has been responsible for repeated assertions in the past that several diseases now known to be due primarily to dietary deficiency were infectious in origin

Systemic Review

Inquiry should be made whether the patient has been conscious of suffering in the past or present from any of the objective manifestations mentioned below under "Physical Examination." In addition, the following subjective symptoms should be considered

Muscles and skeleton Muscular pain, particularly when induced by exercise, is probably an important symptom of thiamin deficiency.⁸ Obscure pains in the extremities may occur in scurvy as a result of periosteal or other deep-seated hemorrhages

Eyes Hemeralopia (night blindness) and nyctalopia (glare blindness) are frequently indicative of vitamin A deficiency.⁷ When corneal or conjunctival lesions due to vitamin A deficiency are present, the patient may complain of a burning, gritty sensation in the eyes

Cardiovascular system Palpitation, dyspnea and swollen legs are usually complained of in heart disease due to beriberi.⁸

Gastrointestinal system Anorexia is an important symptom, since it may in itself be a cause of inanition. In some cases it may perhaps be the

result of thiamin deficiency. A sore tongue is a characteristic symptom of sprue, pellagra and pernicious anemia. Dysphagia occurs in the Plummer-Vinson syndrome associated with iron-deficiency anemia. A burning sensation in the epigastrium may be complained of in pellagra⁹, a common symptom of this disease is diarrhea, which may also be troublesome in nutritional anemias associated with achlorhydria. In mild vitamin B complex deficiency, however, constipation is frequently encountered.⁹ Other gastrointestinal symptoms are significant as evidence of digestive disturbances that may give rise to "conditioned" deficiency.¹⁰

Nervous system Abnormal mental states have meaning both as evidence of influences affecting the intake of food and as symptoms of the mental disturbances of deficiency mentioned below. In nutritional polyneuritis the symptoms of persistent numbness, paresthesia, difficulty in walking and pain in the lower extremities, particularly in the soles of the feet, are of great value in establishing an early diagnosis.¹¹

PHYSICAL EXAMINATION

General Appearance

The general physical condition serves to give an impression of the severity of the disorder

Skin

Much may be learned from an examination of the skin. The following abnormalities should be looked for. An unusually loose or thin skin is often an index of recent weight loss due to alteration in nutritional status. Edema, dependent or widespread, may occur as "hunger edema" due to protein deficiency with hypoproteinemia, and also in beriberi, which may coexist. Dermatitis due to vitamin A deficiency is characterized by hyperkeratotic plugs obstructing the orifices of the sweat glands, and consequent hypohidrosis and dryness of the skin.¹² These changes are usually most prominent on the thighs and upper arms, and give the appearance of persistent goose flesh. Deficiency of nicotinic acid is apparently responsible for the greater part of typical pellagrous dermatitis, which is characterized by hyperkeratosis, pigmentation, desquamation and fissuring, with underlying erythema. The lesions frequently have a "glove, sock and necklace" distribution, and may also be present over the bridge of the nose. It should be remembered that the classic picture of pellagrous dermatitis is rare except in subjects exposed to the sun. Pellagrins who spend much of their time indoors or who live in a sunless climate may show other less typical skin changes.¹³ The dermatitis may be limited to sites subject to mechanical irritation, perianal, labial or scrotal dermatitis is an

example, or intertrigo beneath the breasts. In bedridden pellagrins erythema may appear over the pressure areas—the elbows, knees and hips. In addition there are certain other skin changes which have been recognized⁹ as part of the pellagrous syndrome. These include a fine, branny, scaling desquamation over the trunk and elsewhere, hyperkeratosis over the knees and elbows, a peeling desquamation of the feet (not limited to the areas of pressure) and a type of desquamation, particularly over the legs, giving the appearance of lacquer having been painted on and having cracked, leaving a mosaic pattern. A type of nutritional dermatitis has been described that has been cured by riboflavin. This consists of a scaly, greasy desquamation of the nose and sometimes of the ears and eyelids.¹⁴ Acne rosacea is a useful indication of achlorhydria and consequent increased liability to nutritional disorders, of which it is perhaps a consequence. In some advanced cases of nutritional disease the skin becomes thin, shiny and atrophic. The presence of petechiae or ecchymoses in the skin, associated with other evidence of nutritional disease, suggests deficiency in ascorbic acid (vitamin C) or vitamin K. The latter deficiency is particularly likely if jaundice is also present. In scurvy, minute hemorrhages are commonly present around the hair follicles, especially in dependent areas, and the follicles are sometimes hyperkeratotic, reminiscent of vitamin A deficiency.¹⁵

Hair

An overgrowth of hair over the trunk and sometimes the face occurs in anorexia nervosa¹⁶ and occasionally in undernourished children. It may be an effect of inanition on endocrine activity.

Nails

Spoon shaped, brittle or lined nails may occur in association with nutritional diseases.

Skeleton and Muscles

The bony deformities of rickets and osteomalacia are too familiar to require description. Tenderness of the leg muscles, particularly after exercise, is probably an important sign of thiamin deficiency.⁴ Tetany should be looked for in cases suspected of rickets. Muscular wasting occurs in many cases of malnutrition.

Eyes

Inspection of the palpebral conjunctivae may help in the diagnosis of nutritional anemia. True xerophthalmia is a very rare manifestation, indicative of severe vitamin A deficiency. A commoner sign of vitamin A deficiency is a frosted glass appearance over the scleral conjunctivae.⁴ Unusual

vascularization of the cornea (keratitis) has recently been described¹⁷ as a sign of riboflavin deficiency. Nystagmus and hippus may occur in cases of dietary deficiency associated with alcoholism, and are conceivably a prelude to the severer signs of cranial nerve paralysis occurring in Wernicke's superior hemorrhagic poli-encephalitis. Examination of the fundi may reveal petechiae (vitamin C and vitamin K deficiencies), and is useful to exclude organic diseases of the eye in cases of night blindness in which vitamin A deficiency is suspected.

Mouth

Lips Pallor of the lips is a useful indication of nutritional anemia. Maceration and fissuring at the corners of the mouth (angular stomatitis) and a change at the line of closure of the lips characterized by redness and denudation (cheilosis) have been recognized¹⁴ as manifestations of nutritional deficiency and have been cured by synthetic riboflavin.

Tongue The tongue may be red, painful and swollen in pellagra. In the acute phase of pernicious anemia it may be beefy, red and painful, with or without the smoothness due to loss of papillae that is seen in the chronic stages of this disease. In hypochromic anemia associated with achylia gastrica the tongue may be smooth, flabby, pale and atrophic. An aphthous stomatitis may be present in some cases of dietary deficiency, notably in pellagrins and undernourished children.

Teeth The absence of teeth may predispose to inadequate nutrition. In deficiency of calcium and the fat-soluble vitamins the teeth may show poor development and widespread caries. In scurvy they may be loose, and the gums swollen and bleeding. It is necessary to remember that in edentulous subjects scurvy produces no changes in the gums.

Respiratory System

Laryngeal involvement (laryngismus stridulus) may occur in rickets associated with tetany. Pneumonic infections are common in severe vitamin A deficiency in children.

Cardiovascular System

The most serious nutritional disturbance involving the cardiovascular system is the heart disease of beriberi. This is characterized by tachycardia, cardiac dilatation, edema and peripheral vasodilatation.⁸ The last is manifested clinically by an unusual warmth of the edematous extremities, and is probably responsible for the fact that the blood circulates with greater speed than in nearly all other types of heart disease associated with venous congestion, as can be shown by determining the circulation rate.

Abdomen

Ascites may be present in beriberi heart disease or in "hunger edema." A palpable liver edge or spleen may help in the diagnosis of alcoholism and of hepatic disorders predisposing to vitamin K deficiency. A close search should be made for evidence of gastrointestinal abnormalities possibly responsible for "conditioned" deficiency—abdominal tenderness, palpable masses, operative scars and so forth.

Nervous System

Mental status Undoubtedly the outstanding mental consequences of chronic malnutrition are apathy, spiritual resignation, lassitude and loss of ambition. This fact has probably had a strong influence on the course of human history. Popular social upheavals have usually occurred at times of plenty rather than of poverty. Ships' crews afflicted with scurvy have seldom mutinied. Babies that never give a moment's trouble are not infrequently chronically underfed. The mental calm that comes with starvation is understood in India, and this phenomenon has enabled quacks to earn a considerable livelihood by recommending a diet consisting solely of orange juice.

Other mental disturbances may occur in severe deficiency states. In pellagra there is sometimes a severe psychosis, which may progress to persistent amentia in chronic cases. In beriberi heart disease, restlessness and anxiety are common. Korsakoff's psychosis, characterized by delusions, disorientation and confabulation, is another mental condition that may be associated with gross malnutrition. Finally there are the acute manifestations of delirium tremens, and the stupor of alcoholic encephalopathy and Wernicke's disease, all of which may be associated with malnutrition in alcoholic subjects.

Cranial nerves Nystagmus sometimes occurs in alcoholism. Ocular paralyses are usual in Wernicke's disease.¹⁸ Retrobulbar neuritis may occur in association with severe deficiency disorders.¹⁹

Motor and sensory systems Nutritional polyneuritis occurs in a variety of deficiency syndromes. Though clearly the result of dietary deficiency, it is still by no means proved that it is usually due to lack of thiamin,⁶ as has been frequently claimed recently. Motor changes of polyneuritis may be manifested by loss of ankle jerks, followed by loss of knee jerks and even of the tendon reflexes in the upper extremities. The sensory manifestations of polyneuritis are usually most marked in the lower extremities, and may include any of the following: hyperesthesia, — particularly in the soles of the feet

when the plantar response is elicited, — skin hypesthesia and loss of the vibration and position senses. In pernicious anemia, and also certain conditions associated with severe deficiency of the vitamin B complex, changes in the spinal cord occur that may be manifested by a Babinski sign, altered tendon reflexes and sensory disturbances.

LABORATORY DATA

The following investigative procedures may be of value in individual cases. The tourniquet test is useful in the early diagnosis of scurvy.²¹ X-ray examination of the growing points of the bones may confirm the early diagnosis of rickets and scurvy, and may reveal periosteal hemorrhage as the cause of obscure pain in scorbutic infants and children. X-ray studies are clearly indicated when the deficiency is suspected of being the result of some organic disturbance of the gastrointestinal tract. Complete blood examination is essential when nutritional anemia is suspected. The diagnosis of "hunger edema" must largely depend on the estimation of serum proteins and the exclusion of other causes of edema. The stools should be examined for fat in suspected cases of steatorrhea. Blood or parasites in the stool may afford an explanation in cases of nutritional deficiency associated with an apparently adequate diet. Acholic stools may confirm the diagnosis of obstructive jaundice and consequent predisposition to vitamin K deficiency. The determination of acid in the gastric juice, particularly after the injection of histamine, is a useful indication of predisposition to nutritional disturbances. The diagnosis of vitamin K deficiency is confirmed by the determination of the prothrombin clotting time of the plasma.²⁰ The estimation of ascorbic acid in the blood is some index of the recent adequacy of the diet in respect to this vitamin, but a diminished level of this vitamin in the blood is not diagnostic of clinical scurvy. Methods for estimating other vitamins in the blood and urine and the instrumental measurement of dark adaptation in vitamin A deficiency are at present not sufficiently standardized to be useful for routine diagnostic purposes.

TREATMENT

Once the diagnosis is established the basic treatment is always the same, that is, to alter or increase the diet so that adequate amounts of the factors that are lacking will be provided. In cases where nutritional deficiency has arisen primarily from economic want, it may sometimes be beyond the power of the physician to provide an adequate remedy. But in such cases it is often possible to give definite assistance by suggesting ways in which the family budget can be directed more

economically toward the purchase of an adequate diet. In this connection the help of a social service organization is invaluable. It should be kept in mind that in many cases more benefit is likely to accrue from money spent in the purchase of nutritious food than from that paid to a druggist for expensive vitamin preparations. This is particularly true if the diet has been deficient in protein of good biologic value, on which the supply of essential amino acids depends. But whatever the financial situation, a primary consideration is whether the food is palatable, the art of a good cook is often the best preventive against nutritional disorders.

When there is definite evidence of a moderate deficiency of some particular factor or factors, recovery may be expedited by supplementing the readjusted diet with preparations that provide an additional source of the factors which are lacking. For this purpose it is in most cases best to use crude preparations, cod-liver oil to supply vitamins A and D, yeast concentrate or liver extract as a source of the entire vitamin B complex, fruit juices for vitamin C. Such preparations are not only cheaper but sometimes more effective than purified or synthetic vitamin preparations, since they may contain valuable factors not yet available in purified form. Iron salts and vitamin K, when indicated, are most effectively administered in pure form. Other concentrated preparations—Percomorph and halibut liver oil, synthetic thiamin, nicotinic acid, riboflavin and ascorbic acid—should usually be reserved for the rare cases that present outstanding signs indicative of severe deficiency of some particular factor or factors, for example clinical pellagra, beriberi, scurvy and rickets.

In cases where the deficiency has arisen as a secondary effect of some gastrointestinal disorder parenteral administration of accessory food factors may be indicated. For this purpose synthetic vitamins are valuable, but again, in many cases a crude preparation is to be preferred, and for this purpose unrefined liver extract is most valuable as an injectable source of the vitamin B complex.

The appropriate dosages of the various preparations available have already been discussed in previous articles²²⁻²⁴ appearing in this series, and will not be repeated here.

CONCLUSION

The correct diagnosis of nutritional deficiency usually depends on the clinical appraisal of information obtained from the history, physical examination and laboratory tests. In the absence of a definite diagnosis of deficiency, it is unwise to expect that the administration of concentrated preparations of vitamins will result in any benefit, except possibly some psychological improvement through suggestion. Much nutritional disease may be prevented by the constant watchfulness of the physician, who, by giving advice on the quality and quantity of food to purchase, and even on ways to make it more palatable, may avoid the difficulties of treating cases in which the disorders of malnutrition have advanced to the stage of anatomic and sometimes irreversible changes.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 26181

PRESENTATION OF CASE

First Admission A forty-seven-year-old housewife was admitted to the hospital complaining of infrequent attacks of coma of five years' duration.

The patient was well until five years before admission when she experienced her first attack of increasing weakness and profuse sweating, this was followed by a slowly progressing period of unconsciousness from which she was aroused by an "injection of glucose and caffeine" administered by her physician. She had had seven similar attacks during the five-year period before her hospital entry, and was relieved from each by the injection of intravenous glucose or by a diet high in carbohydrate content. The last attack, her eighth, which occurred some two weeks before admission, was not treated, and she recovered from "coma" after a three-hour interval. It was noted that these episodes were precipitated whenever a meal was missed.

During the same five-year period she also experienced nausea, relieved by vomiting, occurring in spells lasting as long as twelve hours. The vomitus was sometimes watery, and at other times was "bitter, like gall." There was no apparent relation to food or bowel habits, both of which were normal, although her appetite was generally poor. She had lost no weight.

About four years before admission she was ill with "pneumonia," from which she recovered slowly, leaving her with a persistent wintertime productive cough. No hemoptysis or night sweats were noted, although she did on occasions experience slight dyspnea on exertion, palpitation and bilateral chest pain with deep breathing, located mostly in the upper back.

At the onset of the illness five years before entry her physician had made a diagnosis of myxedema—the basal metabolic rate was -42 per cent—and had prescribed thyroid tablets. She took the drug daily (Armour's, 2 gr. in the winter and 1 gr. in the summer), and improved, the basal metabolic rate rising to -6 per cent. She was studied in an outside hospital five months before entry, and she was discharged after a few weeks to her private physician, who again placed her

on thyroid therapy following the last attack of coma two weeks before entry.

The patient lived with her husband and their two children. There had been no miscarriages. Following the birth of her last child seventeen years before admission the previously normal catamenia became "irregular" and infrequent, she flowed about once every six months. The last period had occurred four years before entry, and she apparently had not experienced the "hot flashes" or other stigmas of the menopause.

The remaining family, marital and past histories were non-contributory.

Physical examination revealed a well-developed but somewhat thin, ambulatory woman, in no obvious distress and weighing 93 pounds. The skin was dry and pale, and had a lemon yellow sheen. There was a loss of axillary and pubic hair. The mucous membranes were pale, the mouth was edentulous, and the tongue was smooth and beefy. There was a corneal opacity of the left eye. The chest expansion and lung resonance were normal and equal, but increased tactile fremitus and spoken and whispered voice sounds and amphoric breathing were present in the upper half of the right thorax. No rales, however, were audible. Examination of the heart was negative. The blood pressure was 94 systolic, 64 diastolic. The abdomen was soft and unremarkable. The mucous membranes of the vagina were atrophic. The remainder of the physical examination was negative. There were no areas of pigmentation of the skin.

The temperature, pulse and respirations were normal.

Examination of the blood revealed a red-cell count of 3,120,000, with 74 per cent hemoglobin, a white-cell count of 7600, with a normal differential count, reticulocytes 1 per cent, cell volume 30.8 per cent, volume index 1.18, color index 1.14. The basal metabolic rate was -34 per cent. The serum sodium was 123.4 meq. per liter, the potassium, 8.4 meq., the chlorides, 94.7 meq., the total base, 138.9 meq., the protein, 5.15 gm. per 100 cc., the calcium, 3.3 meq., the phosphorus, 3.3 meq. The plasma volume was 2225 cc., and the interstitial fluid volume was 11,180 cc. The blood Hinton test was positive, but the Wassermann test negative. A sugar tolerance test using venous blood (macrotechnic) was as follows: fast ing, 72 mg. per 100 cc., 30 minutes, 91 mg., 1 hour, 94 mg., 2 hours, 59 mg., 3 hours, 97 mg., 4 hours, 87 mg., 5 hours, 91 mg. A sugar tolerance test using capillary blood (microtechnic) was as follows: fasting, 51 mg. per 100 cc., 1 hour, 89 mg., 2 hours, 61 mg., 3 hours, 101 mg., 4 hours, 93

mg., 5 hours, 100 mg. A gastric analysis showed no free acid after histamine. A quantitative prolan test was negative for 40 units per 100 cc. No follicle stimulating hormone was found in the urine.

Röntgenograms of the chest showed mottled dullness involving both upper lobes as low as the third rib on the left and the fourth interspace on the right. Mottling was rather soft and confluent from the second to the fourth rib on the left, whereas in the other areas it presented a fine honey-combed appearance. Both lung roots were markedly elevated, and the lower portions of the lungs were emphysematous. The heart was unusually small, and what appeared to be the apex was on the right side. The pulsations of the heart, however, were more vigorous on the left side. The aorta and esophagus were in the normal position. The spleen and the gas bubble of the stomach were in the left side of the abdomen. Numerous small gallstones were present within a moderately dilated gall bladder. Films of the skull, the genitourinary and gastrointestinal tracts and the skeleton were essentially normal. An electrocardiogram was negative except for low voltage.

The patient experienced several attacks of coma or semi-coma, which usually occurred in the early mornings or at times when meals were delayed. Food or sugar brought prompt recovery. During these episodes she seemed drowsy and did not respond, although her eyes were usually open, the extremities were "hyperactive," and rarely were moist with perspiration. Save for these attacks, the thirty-nine-day hospital stay was rather uneventful. She was studied thoroughly, however, and treatment consisted of the administration of two pituitary extract preparations (oot on the market), yeast, iron, liver extract, haliver oil and a high-salt diet. She was discharged to her private physician.

Second Admission (two and a half weeks later) She was readmitted for a checkup. During her stay she had a few unconscious episodes similarly relieved by dietary or parenteral administration of glucose. On one occasion the blood sugar before breakfast was 58 mg per 100 cc. The repeat chemical studies were practically unchanged. She became mildly psychotic at one time, but this was relieved by general improvement in nutrition. She ran an otherwise unremarkable course, and was discharged to her private physician on the forty-eighth hospital day.

She remained at home after discharge and seemed to gain weight and to improve generally on a regimen consisting of a high-calorie, high-vitamin diet, the frequent ingestion of salt pills,

small frequent feedings, rare liver extract, vitamin D and iron pills. At one time she was given small amounts of Wilso's cortical extract. She seemed to be fairly well the following fourteen months. About four months before death she began to gain weight, although she had stopped taking salt tablets. Her weakness increased, and following a period of unconsciousness she died seven years after the onset of symptoms.

DIFFERENTIAL DIAGNOSIS

DR ALFRED KRANES Before attempting to answer any of the questions presented by this case I should like to ask a few myself. Can anyone enlighten me on these figures for plasma volume and interstitial fluid volume? Are they high or low?

DR JOHN TALBOTT The plasma volume is slightly elevated. I should think the interstitial fluid volume was essentially normal for the body weight.

DR KRANES The calcium and phosphorus values are somewhat confusing. I am used to seeing them expressed in milligrams per 100 cc.

DR TALBOTT In preparing this abstract I neglected to express these concentrations in the usual way. The serum calcium is 6.6 mg per 100 cc, the phosphorus 8 mg.

DR KRANES Although no urine is recorded I take it a number of examinations were done and were normal.

DR TALBOTT Yes.

DR KRANES May I see the chest plate?

DR OTTO SAHLER There is mottling over both upper lobes, and an extremely small heart, which, in this view, appears to be shifted to the right.

DR KRANES How about the apices? Is there anything to suggest tuberculosis?

DR SAHLER The most likely diagnosis is tuberculosis.

DR KRANES It probably does not have much bearing on the rest of the problem.

The symptoms for which this patient presents herself, namely the attacks of coma, appear to be due to spontaneous hypoglycemia although there is no conclusive proof of that since there is no record of a blood sugar having been taken during an attack. The history, however, seems fairly characteristic. These attacks came on when meals were skipped or delayed, and the prompt relief by parenteral injections of glucose or carbohydrate by mouth plus the extraordinary low blood sugar values and flat blood sugar curve, leaves little doubt that these must have been attacks of spontaneous hypoglycemia. The causes for attacks of this type are relatively few and leave us little in the way of differential diagnosis, it seems to me. The commonest cause is a local

ized adenoma of the pancreas, or generalized hyperplasia of the islet tissue, neither of which can be excluded short of laparotomy. If we make such a diagnosis, however, it leaves too much of the picture unexplained. Inasmuch as a pancreatic adenoma does not explain the whole picture, I should prefer to look elsewhere for the cause of the hypoglycemic attacks.

Another cause of hypoglycemia is extensive damage to the liver resulting in interference with glycogen storage. Cases of this type have been reported with extensive metastatic cancer of the liver or with destruction of the liver due to other causes. In this patient there seems to be no clinical evidence of disease of the liver. To be sure, there was the x-ray finding of gallstones, but they never seem to have caused obstruction of the biliary ducts, and although no liver function tests were done, it seems rather unlikely that a damaged liver was the cause of the hypoglycemic attacks.

So far as I can see, there remains only one other cause, namely anterior pituitary insufficiency. Pituitarectomized animals will frequently exhibit hypoglycemia, and in human beings in whom the pituitary gland has been replaced by tumor tissue, or destroyed by some other process, spontaneous attacks of hypoglycemic coma may also occur. They are extraordinarily sensitive to insulin as well, and this is presumably due to absence of the blood-sugar-raising factor, the diabetogenic hormone, or perhaps the insulin-neutralizing hormone. Just what the mechanism is has not entirely been elucidated.

The more one examines this case the more one's attention is directed at the pituitary gland, and the hypoglycemia is best explained on that basis. This does not seem to be the usual clinical picture of myxedema, despite the very low basal metabolic rate. Myxedema usually responds very well to thyroid substitution therapy, whereas this patient apparently did not improve as one might expect. Despite thyroid administration, the basal metabolic rate on entry was -38 per cent. It would seem, therefore, that we are not dealing with the simple atrophic thyroid gland of myxedema, but rather with a lack of thyrotropic hormone.

Looking further, the menstrual history is a little curious. I should guess from the story that the disease may well have started following the birth of her last child, since symptoms of hypogonadism, namely menstrual periods every six months, began shortly thereafter and at the age of forty-three the periods ceased. That may have been a normal menopause, but she had none of the usual menopausal symptoms. The absence of

hot flashes is rather characteristic of the pituitary type of amenorrhea. Although I realize some patients with a normal menopause may not have hot flashes, nevertheless the majority do. That this was not a normal menopause is further suggested by the absence of follicle-stimulating hormone in the urine. Normal menopausal urines usually contain increased amounts. We, therefore, have evidence of a lack of gonadotropic as well as thyrotropic and diabetogenic hormones.

The blood electrolyte studies are very interesting. They indicate that there may also have been a lack of adrenotropic hormone: there was a low total base with a low sodium and an elevated potassium, the characteristic findings of Addison's disease. Yet one cannot explain the entire picture on the basis of Addison's disease alone.

We have evidence of lack of diabetogenic, thyrotropic, gonadotropic and adrenotropic hormones, and try as I will I cannot make any other diagnosis except complete panhypopituitarism or Simmonds's disease. Most of these patients should be cachectic, but I do not know how cachectic this patient was. It states that she had lost no weight, and yet she weighed only 93 pounds. I wonder whether those who were taking care of her would say that 93 pounds was her normal weight?

DR FULLER ALBRIGHT: She was very thin.

DR KRANES: Had she always been thin? Had she lost any weight?

DR TALBOTT: She had been thin for many years, but I am certain she had lost weight following the onset of illness.

DR KRANES: Cachexia is not necessarily a feature of Simmonds's disease but usually is present. If this is a case of Simmonds's disease, the anterior portion of the pituitary gland should be completely destroyed or replaced by fibrous tissue. The disease frequently starts after childbirth, and from the evidence here, I should guess that it began following the birth of her last child. Her periods soon became very infrequent, but characteristic symptoms did not develop until many years later. Do we know anything about the last labor?

DR ALBRIGHT: No.

DR KRANES: The reason I ask is that frequently this disease occurs following a difficult labor or a labor during which a great deal of blood has been lost. Other causes for destruction of the pituitary gland are tumor, syphilis and tuberculosis. I think tumor is extremely unlikely, since we have no evidence of an expanding lesion in the skull. As for syphilis, the patient did have a positive Hinton test, which apparently was not checked by doing a lumbar puncture. I think it would have been of considerable interest to have

known what the spinal fluid showed. The other possibility is tuberculosis. My final diagnosis is Simmonds's disease, exact cause unknown, and probably a chronic fibrous pulmonary tuberculosis.

Dr. TALBOTT. There were many points of interest about this patient, but I shall comment on only two. She had changes in concentration of constituents of the blood which were characteristic of adrenal insufficiency. She was put on a high salt diet, and responded in a fashion—at least she lived one and a half years on this regimen. I am convinced that her general condition was improved during that time. She received in addition a large amount of carbohydrate, which diminished the attacks of hyperglycemia. The other interesting point was the myxedema. Apparently she had had a low metabolic rate for many years. When we saw her first she had none of the clinical signs of myxedema, but at autopsy she appeared so myxedematous that I failed to recognize her. Thus, she had a basal metabolic rate consistent with myxedema for years, but had clinical signs of the disease only as a terminal affair.

Dr. J. H. MEANS. I think it would be interesting to compare this case with the one Castleman and Hertz* reported. Their case had many of the features present here, but the attacks of hyperglycemia were lacking. We also have a patient on the wards whose case is similar to this but who does not have attacks of hyperglycemia.

Simmonds's disease probably presents a great variety of clinical pictures, and extreme cachexia is not a necessary part of the disease. Dr. K. W. Thompson, with whom I talked recently at New Haven, thinks the amount of food is important in determining the picture. One might have Simmonds's disease without cachexia but with the accent on hypoglycemia. The pattern will vary from case to case, and I think Dr. Kranes's logic is absolutely sound. From the premises given I do not see how one can draw any other conclusion. It would be unusual to see a patient with myxedema who by x-ray shows a small heart, for in this disease, the heart is nearly always enlarged.

CLINICAL DIAGNOSES

Simmonds's disease.
Cachexia
Myxedema.
Adrenal insufficiency
Hypoglycemia.

DR. KRANES'S DIAGNOSES

Pituitary insufficiency—Simmonds's disease.
Chronic fibrous tuberculosis.

*Castleman, B. and Hertz, S.: Pituitary fibrosis with myxedema. *Arch. Path.* 27:69-79, 1939.

ANATOMICAL DIAGNOSES

Cystic atrophy of anterior lobe of pituitary gland.
Simmonds's disease.
Pulmonary tuberculosis, healed, secondary
Atrophy of thyroid gland, adrenal glands and ovaries

PATHOLOGICAL DISCUSSION

Dr. TRACY B. MALLORY. The autopsy showed an extremely small pituitary gland, which consisted almost entirely of posterior lobe. Most of the anterior lobe was made up of a cyst about 4 mm in diameter, and only a few hundred cells were left, there was no extensive fibrosis. We did not run across any thrombosed vessels or any thing to enable us to make a diagnosis of infarction. The other endocrine glands were in general atrophic, the ovaries completely so, but she had passed the menopausal age and that did not mean much. The adrenal glands showed essentially normal medullas with extreme atrophy of the cortices, both weighed only 5 gm. The thyroid gland was also very small, weighing about 5 gm., and showed a marked grade of atrophy with a good deal of lymphocytic infiltration but no scarring, I am quite sure that this was primary atrophy and not the result of a local thyroiditis. The pancreas grossly seemed somewhat small. Microscopic sections—unfortunately we do not know from what spot the specimen was taken—showed a large number of islets. One can never reliably estimate whether the islets are increased or decreased without almost innumerable sections of the entire organ. The parathyroid glands appeared normal. The lungs showed rather extensive fibrosis of the apices, with no caseation or calcification we called it healed tuberculosis, but have no direct proof. The bronchi in that region were dilated. The heart was small, as was predicted, and the other viscera, such as the liver, spleen and kidneys, were correspondingly atrophic.

Dr. PAUL D. WHITE. Was the heart pulled over?

Dr. MALLORY. No, at least not markedly so.

CASE 26182

PRESENTATION OF CASE

A fifty-three year-old single American female hospital worker entered complaining of shortness of breath.

Approximately one month before admission at the onset of her summer vacation following a year's hard work at the hospital, she had had an attack of diarrhea which lasted four or five days. She attributed this to the water supply during the first week of her vacation. Two weeks before admission, after being exposed to bad weather, she developed a cold and a feeling of nausea. The

latter soon disappeared, but the cold persisted. Five days before entry she had another spell of nausea and decided to have her intestinal tract studied when she returned to work at the hospital. That evening, however, she had a sharp chest pain posteriorly. A physician made a diagnosis of pleurisy. She then developed a cough associated with small amounts of foul yellow sputum, and complained of dyspnea and orthopnea. There were no chills. She continued to have severe pain in the right lower chest and was brought into the Emergency Ward in an ambulance.

The family and past histories were noncontributory.

Physical examination showed a well-developed, somewhat obese woman sitting up in bed, slightly cyanotic, and in obvious respiratory difficulty. There was herpes of the lips. The tongue was red and coated. Examination of the chest showed diminished expansion on the right. Anteriorly and posteriorly over the right chest from the mid-scapula down there were increased tactile fremitus and bronchial breathing, rhonchi, moist rales and a friction rub. There were moist rales and rhonchi transmitted to the left chest. The heart sounds were of fair quality. The blood pressure was 140 systolic, 75 diastolic. The abdomen was distended.

The temperature was 102°F (rectal), the pulse 156, and the respirations 28.

Examination of the urine was negative. The blood showed a red-cell count of 5,080,000 with a hemoglobin of 75 per cent, and a white-cell count of 14,850 with 46 per cent mature polymorphonuclears and 46 per cent young forms. The stools were negative. Sputum examination showed Type 1 pneumococcus.

X-ray examination of the chest showed mottled dullness involving the lower half of the right lung field. The dullness obscured the outline of the diaphragm and right border of the heart. There was also a band of dullness extending up the axillary border to the level of the second rib. The left lung field was clear. The heart shadow was not displaced.

The temperature remained between 101 and 103°F for the first four days, and on the fifth day dropped fairly suddenly below 101. A skin test for horse serum was positive, and no anti-serum was given. She became weaker, more toxic and cyanotic, and was put into an oxygen tent. The sudden fall in temperature increased to the time she was placed in the tent. The signs in the lungs increased, the process extending to the right axilla. Scattered rales, some asthmatic and musical, and rhonchi, especially during expiration, were present on the left. The white-blood-cell count rose to 33,000.

formed on the left and thin pus obtained. A stained smear showed pneumococcus. The following day she was transferred to the surgical service and a trocar thoracotomy was performed under local anesthesia. About 100 cc of thin seropurulent fluid was obtained, the culture showed Type 1 pneumococcus. During the next two days she had two chills, each at 2 p.m.

The x-ray film taken on the sixteenth day showed that the process in the right lung was still present and that the area involved was about the same. The outline of the diaphragm, however, was distinctly seen on this side. The appearance was more that of thickened pleura and incompletely expanded lung. The temperature at that time was picket-fence in character, ranging from 99.5 to 105.0°F.

She continued to have chills, became unresponsive and developed edema of the lower extremities. There was a to-and-fro murmur over the heart. No petechiae were seen. She was unable to move the left arm. The knee-jerks were more active on the left. A chest tap in the left eighth interspace on the twentieth day was dry. Another done on the right in the anterior axillary line in the left sixth interspace yielded a few cubic centimeters of pus. An x-ray film taken the following day showed complete drainage of the pleural effusion on the right side. An apical systolic murmur was heard for the first time, but there were no physical signs of pericarditis.

She was transferred back to the medical service on the twenty-first day. The edema was more marked in the left foot than in the right. The left hand was puffy. There were twitchings of the right face. The right arm was spastic, and a Hoffmann sign was present on the right. The apical systolic murmur became loud and high pitched. The blood pressure on the left was 180 systolic, 60 diastolic, on the right 150 systolic, 30 diastolic. She rapidly failed, and died the following day.

DIFFERENTIAL DIAGNOSIS

DR RALPH ADAMS. A history of acute respiratory infection of two weeks' duration, productive of purulent sputum, is presented. Five days before entry, the pulmonary infection was complicated by pleural extension, as indicated by sharp chest pain, and by the development of dyspnea and orthopnea as pleural involvement developed.

The physical examination supported the suspicion of pleural infection by recording a friction rub and moist rales suggestive of pleural edema. Bronchial breathing, increased tactile fremitus, slight cyanosis, and respiratory difficulty also are reported. These findings must be accepted as indication of primary lung disease, characterized by consolidation and the production of purulent

ema, was causing the cyanosis and respiratory difficulty, because empyema, unless massive enough to displace the mediastinum and to collapse the lung, is not productive of obvious respiratory difficulty. The slight cyanosis sometimes associated with empyema is often called "white dyspnea," as distinguished from the "blue dyspnea" of oxygen lack. Proof that the empyema at the time of entry was in an early stage and not massive is furnished by the friction rub. A friction rub can be expected to disappear as sufficient fluid accumulates to separate the pleural surfaces.

The data of the clinical chart, with fever and rapid pulse and respirations, are additional supporting evidence of intrathoracic infection.

Laboratory examination of the sputum identified the clinically recognized pneumonia as due to Type 1 pneumococcus.

The hospital course described is one of pneumococcal pneumonia and pneumococcal septicemia, to which the patient offered no effective resistance. Drainage of the empyema did not materially alter the clinical course. The therapy described suggests that this patient was on the wards before the days of sulfapyridine, and before rabbit antiserum became available as a substitute for horse serum in indicated cases.

Neurological abnormalities appeared late in the course of the disease and as a terminal manifestation of septicemia. They were presumably due to septic cerebral infarcts.

A differential diagnosis in this case is rather hard to elaborate. Underlying cancer must be thought of in any patient with empyema beyond the fourth decade, but no feature of this case is suggestive of cancer of the lung, and the entire record is typical of acute overwhelming pulmonary infection.

CLINICAL DIAGNOSES

Empyema.

Lobar pneumonia, Type 1

Left hemiplegia

Pneumococcal septicemia

Bacterial endocarditis?

DR. ADAMS'S DIAGNOSES

Pneumonia, Type 1

Empyema.

Cerebral thrombophlebitis, with cerebral infarction

ANATOMICAL DIAGNOSES

Endocarditis, acute bacterial, mitral and pulmonary, *Staphylococcus aureus*

Meningitis, acute.

Pulmonary infarct, septic.

Brochopneumonia, resolving

Empyema, right.

Operative wound thoracotomy, right.

Diverticulosis of sigmoid

Cholesterosis of gall bladder

Fibroma of ovary

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. Dr. Adams was of course correct in his surmise that this patient's course in the hospital took place some years ago. She certainly could not, at the present time, have escaped without a trial of chemotherapy. The underlying pneumonia with its secondary empyema was fairly obvious, and the major differential diagnosis lay in attempting to predict the further complications. The medical consultants considered both pericarditis and endocarditis in their effort to explain the murmurs which developed over the cardiac area, and believed that the weight of evidence was in favor of the endocarditis because of the cerebral symptoms. No one ever committed himself as to which valve might be involved.

The postmortem examination showed acute bacterial endocarditis of both the mitral and pulmonary valves, an unusual distribution in the absence of either aortic or tricuspid lesions. On each of the affected valves a large, shaggy, pedunculated mass was found which might easily have functioned as a ball valve. The one on the mitral valve was evidently the older of the two, since it showed considerable organization. That on the pulmonary valve, in contrast, seemed to be quite recent. The lung showed evidence of a resolving pneumonia of the right lower lobe, but also a localized white necrotic area, 1 cm in diameter, surrounded by a hemorrhagic border, which was evidently a septic infarct, almost certainly secondary to an embolus from the vegetation on the pulmonary valve. The empyema had been quite adequately drained by the trocar thoracotomy, and only about 30 cc. of thin, cloudy fluid was found. The other chief finding was in the central nervous system. There was a thick, greenish subarachnoid exudate over the right parietal, the upper part of the left parietal and the medial surfaces of both cerebral hemispheres. It was also found on the base of the brain around the optic chiasm and in the interpeduncular space. Careful throat examination showed no occlusion of any large cerebral artery, and in several sections no small vascular occlusion and no evidence of infarction could be made out. I think we must assume, therefore, that the cerebral symptoms were due to meningitis. Somewhat confusing findings of the autopsy were the postmortem cultures from the blood stream and from the meninges. Both of these showed a pure culture of *Staphylococcus aureus*.

time, and for several years afterward, when general practitioners were not so familiar with diseases of children as they are now, and there were not many well-trained pediatricians, he was in constant demand as a consultant. I remember one morning in 1921 when he was asked to go on six consultations—one in Western Massachusetts, one in Maine, one in New Hampshire, and three in or around Boston. He was a great comfort to the family and to the doctor; he had the power in high degree for sizing up the gist of the situation in a commonsense way and explaining it in such a manner that it could be understood. He made mistakes in diagnosis, as everyone does, if he did, it was never for lack of care. He was very gentle in handling children, and could be scathing to any nurse or house officer who was at all rough.

He was, above all, conservative, probably in his later years too much so. Conservative in accepting new methods in medicine until they had been thoroughly tried, the same in his politics, his investments, his opinions, in every detail of his life. But even after he had become relatively inactive in medicine he read assiduously, observed acutely and kept up with all that was new. Some of the modern ideas he accepted, others he rejected, sometimes he was right, sometimes wrong. He was not an obstructionist, he was not opposed to new theories as such, but he found it hard to accept them wholesale, particularly if various procedures might not be really necessary or might do harm to the child.

His attitude in this respect was, during his later years, somewhat exaggerated, but it did no harm. With his long experience he realized that fads come and go, and with his inborn caution he was chary of accepting anything new unless its worth had been fully demonstrated. Once he became convinced of the value of a new procedure, he became its friend, and was equally reluctant to let it go, if it had served him well. His office desk, until he retired, was the same one he had used in college, the calendar stand on his desk had been used by his grandfather, his chauffeur had started with him in 1906 when he bought his first automobile. Although he hated waste, and would save a piece of string rather than throw it away, his clothes came from one of the most expensive tailors, and his shoes were always made to order, of the finest materials, not because he liked expensive things as such, but because he thought they would last longer. If a thing or an idea worked, if it was good, he wanted to keep it, no matter how many new ones were available. His tastes were very simple, his whole outlook was frugal, it was abhorrent to him to spend money

foolishly, yet he was very generous, gave each year a large sum to the associated charities, and was scrupulously fair in all his financial dealings.

One of his chief characteristics was his consistency. If he had been in the habit of doing a thing or reacting to a situation in a certain way he would do the same thing again, and anyone who knew him well could predict with considerable accuracy how he would think or act. He was utterly reliable; if he said he would do a thing, he would do it. Most men are honest in the sense that they do not steal; not so many are intellectually honest—he was. He never permitted what he or anyone else thought ought to be so to sway his judgment if the facts were against it. As a rule, he did not make up his mind quickly, not because he did not know what he wanted, but because he wished to consider a matter in all its aspects before he formed an opinion on it. No one who did not know him well can realize how often his advice was sought, or how highly it was valued.

He was somewhat reserved in manner to those he did not know well, but underneath this reserve he was in reality a very friendly and sociable personality and enjoyed being and talking with other people. He had a keen sense of humor, and nothing pleased him more than a funny situation or story. He was by nature tactful, when tact was necessary, but was entirely independent and fearless in saying what he thought, no matter whether those whom it concerned liked it or not. Twenty-five years ago discussion in medical meetings was often more acrimonious than it is today, and inasmuch as when a paper did not please him he never hesitated to say so, often in a somewhat caustic manner, he sometimes made enemies. He was fond of saying nothing until everyone else had had their say, then he would sum up the situation, and if the discussion had been irrelevant, dull or foolish, he would let the gas out of the balloon with a few sharp comments.

If anyone had done him a kindness, he never forgot it, if an injury, he never forgot that, and could be vindictive toward anyone whom he thought had tried to harm him.

Medicine was of course his main interest, but he was by no means a man who did not know how to play. Before he was married, he did a good deal of big game shooting, particularly moose, and in the days of the poker coterie at the old University Club was a formidable player. He had an ideal family life. Mrs. Morse was his constant companion, he always talked over with her the many problems of administration and organization he had while he was actively engaged in hospital

work, and relied a great deal on her advice. He cared little for art, the theater, music or literature, but was devoted to nature, and at his small farm house in Wayland, where he went every week end, he took great delight in putting about at odd repair jobs and in observing and absorbing the things of outdoors—birds, of which he was very fond, trees and flowers. In the summer, he went for many years to Shelburne, New Hampshire, where he did about what he did at Wayland.

"Johnny" Morse was loved by all those who knew him well, particularly, as he grew older, by medical men younger than himself. A group of about thirty of these gave him a dinner on his seventieth birthday. At this dinner a poem was read which closed with the following lines

John Lovett Morse, by thee we set great store
Respect thee much, and love thee more.
A human true and kindly friend thou art,
A life well lived—thou st nobly done thy part.

SECTION OF OBSTETRICS AND GYNECOLOGY*

RAYMOND S. TRUSS, M.D., *Secretary*
330 Dartmouth Street
Boston

PYELITIS IN PREGNANCY

Mrs. B., a twenty nine year-old para II, was first seen in the office on January 27, 1923, when about nine weeks pregnant.

There was no history of familial diseases. The patient gave a history of scarlet fever, with no sequelae, at the age of six and of measles. There was no history of serious illness or operations. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted five days. The last period had begun on November 21, 1922, making the expected date of confinement August 28. The first pregnancy had been normal and had ended in a simple forceps delivery on August 17, 1918.

Physical examination showed a well-developed and nourished woman. The weight was 118 pounds, the patient having lost 5 pounds in two weeks. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The blood pressure was 126 systolic, 60 diastolic. The breasts showed slight engorgement. Vaginal examination revealed a cervix

that was soft and posterior, the fundus was anterior and enlarged. A specimen of urine was negative.

The pregnancy progressed normally with a normal blood pressure and a negative urine until May 19. At this time the patient weighed 131 pounds there was no edema and the blood pressure was 120 systolic, 60 diastolic. She complained of a severe pain in the region of the right kidney, but there was no fever. A specimen of urine procured a few days later showed a trace of albumin and 100 to 200 white cells per high-power field. At this time the temperature was ranging from 99°F in the morning to 103 or 104 in the afternoon. There was definite tenderness in the region of the right kidney, but no particular difficulty with micturition. From then until June 8 the temperature fluctuated between 98 and 103°F., with occasional chills. Treatment had been entirely symptomatic. Fluids were forced, and an ice bag was placed over the kidney. Urotropin was then given in 7½-gr doses four times a day for three days, and then sodium bicarbonate was prescribed to alkalinize the system. She was seen in consultation by a urologist, whose advice was entirely conservative—no thought of renal lavage entered the minds of the medical profession at that time. The consultant said that the condition might keep up, and on until the arrival of the baby, after which he believed that the pyelitis would clear up spontaneously.

By June 16 the temperature was approaching normal. The patient had lost a great deal of weight, had no appetite and felt very poorly. There was still some tenderness in the region of the right kidney. The urine showed a trace of albumin and 50 to 100 white cells per high-power field. Nature was extremely kind in this case, because from July 1 until September 4, when labor started, the urine was comparatively free from pus, and the patient had no fever and gradually recovered her appetite and general sense of well-being. She was delivered on September 4, and had a perfectly normal convalescence.

After that the patient never had other attacks of pyelitis. A specimen of urine taken on August 6, 1928, showed the slightest possible trace of albumin with 1 to 3 leukocytes per high-power field and no casts. The blood pressure was not elevated.

She was not seen again until October 27, 1930, when the blood pressure was 220 systolic, 126 diastolic. The urine showed the slightest possible trace of albumin, and the sediment contained no red cells or leukocytes but an occasional granular cast.

The patient continued to run a high blood pres-

*A series of selected case histories by members of the section will be published early. Comments and questions by subscribers are solicited and will be discussed by members of the section.

sure until she died suddenly of a cerebral hemorrhage in 1935

Comment This case illustrates perfectly the conservative treatment of pyelitis in 1923. The treatment consisted of rest in bed, forced fluids and urotropin and sodium bicarbonate by mouth, and only very infrequently did the condition become so grave that interruption of the pregnancy was entertained. It was often very difficult to get sufficient nourishment into these patients because not only did the continued fever do away with all desire for food but persistent vomiting often resulted in the loss of much of the food ingested. The intravenous injection of glucose solution was not a common form of medication, and subcutaneous injections of saline were frequently necessary to maintain a normal fluid intake. It was the common belief then that when pyelitis occurred during pregnancy it spontaneously cleared after the baby was delivered, that subsequent attacks of pyelitis were uncommon and that true kidney damage as a result of pyelitis did not occur. All this we now know to be untrue. It is fair to infer that the sustained blood pressure which subsequently developed was based on damaged kidneys as a result of the pyelitis. Pyelitis during pregnancy is not the innocuous disease that it was considered to be fifteen or twenty years ago.

CHOOSING A CAMP FOR YOUR CHILD*

The camping season will soon be here, and the important question for parents to decide is whether they want their children to go to camp this summer. Those who have sent their children in the past will have little difficulty in making this decision if their children have not passed the camping age. These parents realize that the benefits which their children receive from camp are far greater than those they would receive at home, regardless of whether they live in the city or the country.

All parents should know what summer camps attempt to do for their children. Camps in reality are like schools and teach children how to live happily together under delightful natural surroundings. They are not merely places where parents can send their children to avoid the heat of the summer. They are character-building institutions where boys and girls learn principles of right and wrong through the example and leadership of their counselors. Instead of learning to read and write, they learn the various summer sports, such as swimming and boating, and craftsmanship. The modern camp is giving up the strict regimentation of school life, and although there is discipline, boys and girls are allowed to pursue their own interests. Children now may engage in projects of their own, which often give them the inspiration of accomplishment. One cannot pass over lightly the great part that the country, with its beautiful trees, its lakes and all the mysteries of nature, gives to children. The love of

the great out-of-doors which New England affords so liberally is something to which every child is entitled.

A word should be said about the general camp situation in Boston and New England. In the first place we are situated in one of the most ideal localities for camps, with the ocean, lakes and country at our very doorsteps. The unfortunate part about it is that there are still far too few camps for all the boys and girls who ought and want to go to one. There are in general two classes of camps, which might well be compared to public and private schools. The public ones are often called organization camps because they are financed and directed by public spirited men and women who wish to give camping experience to all boys and girls without respect to the finances of their parents. These people believe that camp life should be afforded to all children, just as education is given to all children. There are about seventy such camps, some large, some small, which emanate from Boston alone. Some of these are the scout camps, the Salvation Army Camp, the East Boston Settlement House Camp, and the News Boys' Camp. All these and many others have been examined, visited and revisited by people interested in camps for children, and many friendly criticisms and suggestions have been made, with the result that the standards have been greatly improved, that is, there are better buildings, councilors, programs and food and a longer stay in camp.

Some of us are very much interested in the physical side of camp life. We do not believe that this is more important than programs and personnel, but we do believe that no camp should take the responsibility of caring for children without providing adequately for certain essential physical conditions. These include the proper situation for the camp site, proper sewage disposal and drinking water free from contamination. These matters cause us little thought in our cities because public health departments and sanitary engineers have made them a part of our life, but camps must have the same systems, which are expensive essentials. In some states, sewage disposal and pure water supplies are controlled by laws, in others only superficial supervision is given, while still others are entirely under the direction of the camp authorities. We believe from our studies that most New England camps have safe water and proper sewage disposal plants, and we are not aware that any diseases among campers have arisen from these sources.

The camp buildings should provide proper shelter against cold and rainy weather, proper space for sleeping and adequate recreational rooms. One of the most important buildings is the kitchen, and there should be good refrigeration facilities.

The diet for campers is a subject that concerns us a great deal. It is true that many children remain in camp only two weeks, so that little harm can come from poorly balanced and insufficient food, but even so, the diet should be perfect in order to give the camper the best results. We have not established the ideal menus for camps, and more work must be given this subject. The most expensive diet certainly is not always the best. We have sampled a good many camp diets, and although there are exceptions, most camps are providing good food for the children. Some of the camps have used local raw milk in the past, but pasteurized milk is much more desirable and now, I understand, is prescribed by law for all campers in one New England state.

Among the important physical requirements for camps which should interest every parent is proper medical supervision. Health in a camp is not only important for each camper but for the group. If one child has an in-

*A Green Lights to Health broadcast given by Dr. Warren R. Sisson on Tuesday April 9 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

fection it may spread to others. This means, first of all that every camp should have a physician in residence or near enough so that he can make regular visits and supervise and instruct the camp staff in medical matters. A qualified nurse should live in every camp and be able to care properly for any sick camper and attend to minor injuries. Her presence adds greatly to the security of your children while they are away from you.

All campers should have a physical examination before going to camp to be certain that they are free from any infection and to find out if they are qualified for camp life. They should all be examined again on arrival in camp in order that every child's physical condition may be known first hand to the camp physician and to the director and his staff. Parents should also know that these physical examinations are important for all the staff and food handlers, as this gives added protection to the children's health.

Q How shall I go about selecting a camp for my two girls, aged ten and twelve?

A. That is just the question hundreds of mothers are asking, regardless of the type of camp. You may not know that there is a camp division of the Boston Council of Social Agencies at 80 Federal Street (LIB 8515)

Q Is this a directory for the organization camps?

A. Yes, and anyone may call up there to find out all about them. The secretary of this office will tell you about the camps and where to apply

Q Will he know whether these camps have fine counselors and good food for my girls?

A. Yes, because he has visited most of them.

Q What do you think is the most important thing to consider in selecting a camp for my girls?

A. You have asked me a very hard question but I believe if a camp has a good director who is always on the job his camp will be suitable for your children.

Q But how can I see the director and how can I tell if he knows how to manage a good camp?

A. Many times you can see the director. This is always true of the private camps and you can always ask your friends and their children who have been to camp about the director. If a camp has a good reputation among campers, it generally means that the director is good.

Q In selecting a camp should I inquire into all these things which you have mentioned such as pasteurized milk, refrigeration, a camp doctor and nurse?

A. Yes, I think you should ask about some of these things at least. If they have these essentials they will have the rest. Furthermore, if you ask these questions it will emphasize the importance of high standards for the successful future of their camps.

Q One of my girls has had a great many colds this past winter. Do you think she ought to go to a seashore camp or to one in the mountains?

A. I do not believe it really makes much difference. The important thing is to select a well run camp.

Q If I or one of my friends could afford to pay the full camp fee or tuition of a private camp, how would you select the proper one?

A. I think I should use the same rules. There is a directory for private camps, published by the American Camping Association in Chicago, but it will not help you much. I am certain that I should not select a camp on

social grounds—as many people do. I should ask my physician, a teacher I respect in my child's school or some friend who knows about camps.

If you start now to investigate the camps available to you you will find a good one for your children and they will have one of the best summers in their lives and be healthier, happier and more useful people in later life.

DEATH

LOVELL—MARTHA E. LOVELL, M.D., of Boston, died April 22.

Born in Ludlow, Vermont, she received her education at Black River Academy and obtained her degree from the Woman's Medical College of Pennsylvania in 1899. Dr. Lovell served her internship at the New England Hospital for Women and Children.

She was staff physician of the Massachusetts Society for the Prevention of Cruelty to Children for thirty-two years having become associated with that organization in 1906.

Among her affiliations were memberships in the Massachusetts Medical Society and the American Medical Association.

A sister Dr. Lucinda Lovell, and three brothers survive her.

MISCELLANY

ASSOCIATED HOSPITAL SERVICE CORPORATION

The increasing financial soundness of the Blue Cross of Massachusetts is indicated in its annual statement for 1939 which was recently released by the executive director Mr. R. F. Cahalane. The organization started 1939 with a deficit of \$7,252.84 and ended with a surplus of \$152,359.73 according to the statement. Over 76 per cent of the earned income, or \$1,109,425.28 was paid out for hospital service to subscribers during the year. Within this year the accrual method of accounting for earned income was adopted, the statement explained.

General operating costs were 87 per cent and the cost of acquiring new members, servicing accounts and conducting a public education program was 2.5 per cent, making a total of 11.2 per cent of earned income for administration and operation. "This is one of the lowest operating costs among the sixty service plans now approved by the American Hospital Association," Mr. Cahalane declared. "Operating costs are kept at this low level because all employees of the Blue Cross, including staff representatives, work on a salary basis with no commissions or bonuses paid," he explained.

In commenting on the newly acquired surplus or reserve fund Mr. Cahalane said "Our experience last year with an epidemic of respiratory infection, when it was necessary to make deductions on hospital bills, showed us that it was increasingly desirable to create a reasonable reserve to provide against any such future emergency. When the reserve fund is deemed sufficient, further surplus will be returned to subscribers in the form of added benefits or decreased membership rates. The Blue Cross has repaid its member hospitals half the amount of the deductions made last spring and expects to pay the remainder after the winter months have passed. The original loan for initial working capital was repaid in December 1938."

He added "During two and a half years of operation we have forged steadily ahead, in spite of a few growing pains. The number of subscribers enrolled has exceeded all estimates made at the beginning. We have every reason to look ahead to substantial growth and the extension of

Blue Cross service to larger numbers of citizens, particularly those in the lower income groups"

* * *

The balance sheet, as of December 31, 1939, is as follows

| ASSETS | |
|--------------------------------------|--------------|
| Cash in banks and on hand | \$488,935 65 |
| Accounts receivable | 49,099 01 |
| Deposits in savings banks | 25,314 97 |
| Total assets | \$563,349 63 |
| LIABILITIES AND RESERVES | |
| Reserve for hospitalization expenses | \$179,554.91 |
| Accounts payable | 1,484 20 |
| Unearned subscriber payments | 229,950 79 |
| Operating reserves | 152,359 73 |
| Total liabilities and reserves | \$563,349 63 |

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR FEBRUARY, 1940

| DISEASES | FEBRUARY 1940 | FEBRUARY 1939 | FIVE YEAR AVERAGE* |
|--------------------------|------------------|------------------|-----------------------|
| Anterior poliomyelitis | 2 | 0 | 0 |
| Chicken pox | 1705 | 1347 | 1363 |
| Diphtheria | 15 | 12 | 22 |
| Dog bite | 648 | 580 | 534 |
| Dysentery bacillary | 41 | 23 | 7 |
| German measles | 60 | 66 | 511 |
| Gonorrhea | 291 | 285 | 383 |
| Lobar pneumonia | 581 | 616 | 675 |
| Measles | 1193 | 3819 | 2541 |
| Meningococcus meningitis | 5 | 7 | 11 |
| Mumps | 668 | 823 | 968 |
| Paratyphoid B fever | 0 | 2 | 1 |
| Scarlet fever | 511 | 890 | 984 |
| Syphilis | 405 | 343 | 424 |

| Tuberculosis other forms | 34 | 12 | 24 |
| Typhoid fever | 6 | 5 | 5 |
| Undulant fever | 4 | 2 | 3 |
| Whooping cough | 534 | 1015 | 895 |

*Based on figures for preceding five years

RARE DISEASES

Anterior poliomyelitis was reported from Boston, 2, total, 2

Diphtheria was reported from Andover, 1, Boston, 3, Lawrence, 1, Methuen, 2, Peabody, 2, Saugus, 1, Shirley, 1, Somerville, 2, Worcester, 1, Wrentham, 1, total, 15

Dysentery, bacillary, was reported from Boston, 1, Cambridge, 4, Lowell, 1, Lynn, 2, Medfield, 10, Merrimac, 1, Pittsfield, 8, Salem, 8, Westfield, 5, Wrentham, 1, total, 41

Infectious encephalitis was reported from Merrimac, 1, total, 1

Malaria was reported from Watertown, 1, total, 1

Meningococcus meningitis was reported from Boston, 1, Falmouth, 1, Holyoke, 1, North Adams, 1, Tewksbury, 1, total, 5

Pfeiffer bacillus meningitis was reported from Hanson, 1, total, 1

Septic sore throat was reported from Andover, 1, Belmont, 1, Boston, 2, Cambridge, 5, Danvers, 1, Fall River, 2, Greenfield, 2, Haverhill, 2, Merrimac, 1, New Bedford, 1, Peabody, 1, Revère, 1, Somerville, 1, Watertown, 1, Wrentham, 1, total, 23

Trachoma was reported from Boston, 1, total, 1

Trichinosis was reported from Boston, 1, total, 1

Typhoid fever was reported from Arlington, 1, Brockton, 1, New Bedford, 1, Salem, 1, Swampscott, 1, Weymouth, 1, total, 6

Undulant fever was reported from Brookfield, 1, Haverhill, 1, Stockbridge, 1, Worcester, 1, total, 4

Chicken pox had its highest February incidence since 1916

The reported incidence of dog bites was slightly above the five-year average, with the highest February incidence since 1928

There is a continuation of the slight upward trend of bacillary dysentery, primarily of the Sonne type.

Diphtheria was reported at expected levels, the slow upward trend of the past five months being broken.

Scarlet fever had its lowest February incidence since 1906

German measles, gonorrhea, syphilis, measles and mumps were reported well within the five year average.

Lobar pneumonia, meningococcus meningitis and whooping cough were reported at expected levels.

There was nothing remarkable in the reported incidences of anterior poliomyelitis, paratyphoid B fever, tuberculosis, typhoid fever and undulant fever

MAINE NEWS

MAINE MEDICAL ASSOCIATION

The eighty-eighth annual session of the Maine Medical Association will be held at Rangeley Lakes, Sunday, Monday and Tuesday, June 23, 24 and 25

Monday afternoon will again be devoted to a clinic-pathological discussion. An added feature will be a discussion of the use of sulfapyridine and allied compounds by a recognized authority. In the evening the ever popular dinner-dance is planned, and Mr V W Peterson, of the Federal Bureau of Investigation, is to speak.

Tuesday afternoon, Drs Henry Marble and Timothy Leary, of Boston, and Dr P L B Ebbett, of Houlton, are to talk on subjects of general interest. Governor Barrows will speak following the banquet in the evening as will Dr Morris Fishbein, editor of the *Journal of the American Medical Association*, for the second successive year. The title of the latter's talk will be "Quackery in Medicine"

MAINE PUBLIC HEALTH ASSOCIATION

The Maine Public Health Association held its 1940 Campaign for the Prevention of Tuberculosis during the month of April, for the thirteenth consecutive year. The slogan was "The X ray Reveals Tuberculosis before the Symptoms Appear," the object being to teach the importance of using the x ray as a necessary tool in securing an early and correct diagnosis.

Especially co-operative agencies were the Maine Federation of Women's Clubs, the Maine Medical Association, district health officers, Red Cross agencies, milk dealers, various educational institutions, and newspapers. Broadcasts were arranged, women's clubs distributed literature, milk dealers used bottle caps carrying the slogan, industries enclosed literature in pay envelopes, announcements were made through the churches on Early Diagnosis Sunday. Inmates in sanatoriums who were able were asked to write letters to friends urging health check-ups with x ray studies.

WOMEN'S FIELD ARMY OF MAINE

Prior to 1937 no financial provision had been made either by the State or by the hospitals, for the treatment of needy tumor patients. Realizing this fact the Women's Field Army of Maine established the Dr Joseph W

Scannell Memorial Fund for the treatment of indigent tumor patients by x-rays or radium—two of the most expensive and essential items in the control of the disease.

Since the inauguration of the Women's Field Army in 1937 records show a constant increase in the attendance at the tumor clinics, which are conducted at the Maine General Hospital (Portland) the Eastern Maine General Hospital (Bangor) the Thayer and Sister's hospitals (Waterville) and the Central Maine General and St. Mary's General hospitals (Lewiston). In 1937 to 1938 600 patients were examined at the six clinics of this number the Women's Field Army assisted in financing the treatments for 147. From May 1 1938 to May 1 1939 approximately 950 patients were examined at the clinics, 309 cases being assisted by the Women's Field Army. From May 1 1939 to May 1 1940 750 patients were examined, and 222 cases were assisted by the Women's Field Army. Of the number of patients coming to the clinics a greater proportion are coming early and are therefore curable cases.

The personnel of the Women's Field Army is as follows: state commander secretary 16 vice-commanders, 16 deputy vice-commanders 142 majors of districts, who secure captains in the cities and towns, and a publicity director (part time). A million pieces of literature are distributed and 2000 booklets and letters to the doctors and ministers of Maine. A goal of \$25,000 has been set for the 1940 campaign. The Maine Legislature has appropriated \$5000 for the fiscal years ending June 30 1940 and June 30 1941.

CORRESPONDENCE

MEDICAL SPECIALISTS

To the Editor: Your comments on the recently issued *Directory of Medical Specialists* and on the general subject of certification of specialists appearing in your issue of March 28 were of great interest to all of us concerned with this movement.

Your criticisms were, as usual in your editorial columns constructive ones, and I desire only to clarify certain points about which there seems to be some misunderstanding.

The general impression seems to prevail suggested again in your editorial that the special examining boards require all applicants for certification to obtain their training solely by prolonged periods of hospital residency services, amounting to from three to seven years of such service. This is not correct, and the preceptorship or assistantship method of training is acceptable to all the boards.

A quotation from the requirements of the American Board of Surgery reads as follows: "One may secure the necessary training as an assistant to an accredited surgeon, provided suitable facilities for the education of the candidate are offered." Combinations of hospital residency and staff assistantship trainings are also entirely acceptable, the minimum period of such training in general surgery being specified as five years.

Your editorial suggests that two years of hospital training after the intern year should be sufficient for this but the Board of Surgery believes the surgeon with such relatively scanty training would lack maturity of judgment and experience and would not be sufficiently safely grounded to warrant his being certified as a recognized specialist in general surgery.

The regulations of the American Board of Obstetrics and Gynecology state: "As a substitute for special [hos-

pital] training service with a qualified preceptor may be acceptable. The time [required] for this type of training will vary with the amount of work done with the preceptor [but must be at least three years]."

It is clear from the foregoing that dispensary staff appointments, as well as assistant or associate staff appointments in accredited hospitals under proper supervision, may be utilized by candidates as fulfilling training requirements when opportunities for the more intensive residency system training have been lacking.

As one who has served for ten years as an examiner for one of these boards, may I refute that "the examiners have on some occasions been more interested in limiting the number of certificate holders than in determining the fitness of the individual candidate?" Such comments have been heard from thoughtless or unsuccessful candidates but are entirely unjustified. On the contrary every Board strives for the opposite, namely to approve as many as can really qualify. Far more time is taken with questionable candidates than with any others. Such men are given every additional opportunity to qualify when their first showing has been uncertain or poor by being questioned by several rather than by only one set of examiners.

I have repeatedly sat with other examiners and heard the candidate asked a controversial question about which the examiners themselves disagreed regarding the answer. The candidate was told this and that we wanted to know his opinion and by what reasoning he came to his conclusions. Under such circumstances I have never seen a candidate failed on his answer merely because it disagreed with the opinion held by one or two of us provided his knowledge of the subject and his lines of reasoning justified his opinion. This, to my mind, is a real type of examination.

The *Directory of Medical Specialists* was prepared primarily for the medical profession as a means of distinguishing by certification formally qualified specialists from others whose claims to be specialists may be valid or merely their own self-appraisals. We hope the profession will use the directory rather than the lay public, as reference of patients should be by the former not by the latter.

However and as you suggest, the public is certain to be come actively aware of this movement to elevate the practice of the medical specialties. In this instance, the medical profession is once again trying to lead rather than to follow the lay public in the better care of its sick population.

PAUL TITUS, M.D. Secretary
Advisory Board of Medical Specialists.

Pittsburgh Pennsylvania.

ULTRA VIOLET CURTAINS

To the Editor: The editorial "Ultra Violet Curtains" in the April 11 issue of the *Journal* might have more strongly emphasized the epidemiologic point that the reservoir for respiratory infection is not the atmosphere, but the nasopharyngeal membranes of the people who breathe it. Like wise in the Wells experiment, the reservoir is the atomizer not the air it pollutes. Sterilized air is just as good a vehicle between individuals as is polluted air. This concept is presented in a report on the epidemiology of respiratory infection in the *Bulletin of the New England Medical Center* 2:290-94 (1940).

MEDICAL CONFERENCE PROGRAM, MAY-JUNE

Friday, May 3—A Review of Diabetes. Dr Elliott I Joslin.
Saturday, May 4—Hospital Case Presentation. Dr James E Paullin
Thursday, May 9—Research in the Control of Cancer Pain with Special Reference to the Newer Morphine Derivatives. Dr Lyndon E Lee.
Friday, May 10—The Management of the Pernicious Anemia Patient with Neural Disturbance. Dr William P Murphy
Saturday, May 11—Hospital Case Presentation. Dr S. J. Thannhauser
Tuesday, May 14—Studies in Urobilinogen Metabolism. Drs Karl Singer and Edward B Miller
Wednesday, May 15—Hospital Case Presentation. Dr S J Thannhauser
Thursday, May 16—Huntington's Chorea. Dr A. Warren Stearns
Friday, May 17—Obesity. Dr Mark Falcon Lesser.
Saturday, May 18—Hospital Case Presentation. Dr S. J. Thannhauser

Tuesday May 21—Arthuric Clinic. Dr. Walter Bauer
 Wednesday, May 22—Hospital Case Presentation. Dr.
 S. J. Thannhauser
 Thursday, May 23—Cardiac Clinic. Drs. H. Magen-
 dantz and A. Zetlin.
 Friday May 24—The Origin, Diagnosis and Treatment
 of Pituitary Body Tumors. Dr. Oscar Hirsch.
 Saturday May 25—Hospital Case Presentation. Dr.
 S. J. Thannhauser
 Tuesday May 28—Personality Factors in Internal Medi-
 cine. Dr. C. Macfie Campbell.
 Wednesday May 29—Hospital Case Presentation. Dr.
 S. J. Thannhauser
 Friday May 31—Changes in the Circulation Produced
 by Poor Postural Adaptation. Dr. Eugene A. Stead, Jr.
 Morning conferences will be resumed on Tuesday, Oc-
 tober 1, 1940.

CARNEY HOSPITAL

The monthly meeting of the John T. Bottomley Society
 will be held at the Out Patient Department of Carney Hos-
 pital on Tuesday, May 7 at 11.30 a.m. Dr. S. Tracy
 Clarke will speak on the subject "Medical Ophthalmology"
 Physicians and students are cordially invited to attend.

BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held
 at the Boston City Hospital on Wednesday May 8, at
 12 o'clock noon in the Pathological Amphitheater

HARVARD MEDICAL ALUMNI ASSOCIATION

The annual meeting and dinner of the Harvard Medi-
 cal Alumni Association will take place on Wednesday
 June 12, at 7.15 p.m. at the Harvard Club of New York
 during the annual session of the American Medical Asso-
 ciation. The speakers will be President James B. Conant
 and Drs. C. Sidney Burwell, Lincoln Davis and Cornelius
 P. Rhoads. Notices with return cards will be sent to all
 alumni in advance.

PETER BENT BRIGHAM HOSPITAL

A joint medical and surgical clinic at the Peter Bent
 Brigham Hospital will be held on Wednesday May 8
 from 2 to 4 p.m. Drs. Robert Zollinger and E. S. Emery
 will speak on "Diarrhea and Constipation."
 Physicians and students are cordially invited to attend.

SOUTH BOSTON MEDICAL SOCIETY

The annual dinner of the South Boston Medical Society
 will be held at the Harvard Club on Monday May 20 at
 7.00 p.m. In celebration of its thirty-fifth anniversary the
 history of the society will be read

Reservations for the dinner may be made by telephoning
 Dr. John T. Foley SOU 1617

BOSTON LYING-IN HOSPITAL

The Journal Club will hold its next meeting at
 the Boston Lying-In Hospital on Tuesday May 14 at
 8.15 p.m. Dr. George L. Streeter of the Carnegie Insti-
 tution, Washington District of Columbia, will speak on
 "Important Factors in Development as Revealed by Early
 Stages of the Macaque Embryo."
 Physicians and students are cordially invited to attend.

NEW ENGLAND PEDIATRIC SOCIETY

The next meeting of the New England Pediatric Society
 will take place on Wednesday May 15. The clinical
 presentation will be held at the Massachusetts General
 Hospital and all the other events at Longwood Towers,
 Brookline.

PROGRAM

- 4.00 Clinical presentation by staff at Massachusetts
 General Hospital.
- 6.15 Refreshments.
- 7.00 Dinner
- 8.15 Symposium on Adolescence.
 Psychological Disturbances and Adjustments
 of Adolescence. Dr. James S. Plant, New
 ark, New Jersey
 Scholastic Difficulties of Adolescence. Mr.
 C. E. Allen.
 Disturbances of Menstruation and Ovulation
 of Adolescence. Dr. John Rock.

Physicians are cordially invited to attend the clinical
 meeting and the symposium.

MASSACHUSETTS SOCIETY OF EXAMINING PHYSICIANS

The annual meeting of the Massachusetts Society of Ex-
 amining Physicians will be held at the Copley-Plaza Ho-
 tel Boston, on Wednesday, May 8. Dinner will be served
 at 6.30 p.m. at \$2.50 per plate.

PROGRAM

- Business.
- Election of officers.
- Election of candidates for membership.
- The Treatment of Dupuytren's Contracture on the
 Second Surgical Service of the Carney Hospital.
 Dr. William E. Browne.
- The Work of the Board of Registration in Medicine.
 Dr. Francis R. Mahony
- A Quarter Century Experience with a Benefit Plan
 for Twenty Thousand Employees. Dr. Daniel
 L. Lyoch.

ASSOCIATION OF MILITARY SURGEONS

The Colonel Williams Chapter of the Association of
 Military Surgeons of the United States will hold its second
 meeting of the year at the Worcester State Hospital,
 Worcester on Friday May 10 at 8.00 p.m. Dr. William
 Malamud will speak on the subject "The Treatment of
 the Neurosis in General Practice." The meeting will be
 preceded by the election of officers for the coming year

AMERICAN COLLEGE OF CHEST PHYSICIANS

The sixth annual meeting of the American College of
 Chest Physicians will be held June 8, 9 and 10 at the Hotel
 Baltimore, New York City. The first day Saturday,
 June 8 will be devoted to papers by members of the
 Medical Section with an "Information Please" luncheon.
 On Sunday June 9 an administrative session will be held
 in the morning and a meeting of the Surgical Section
 in the afternoon, with another "Information Please"
 luncheon. On Monday June 10 clinics will be given at
 the Lenox, Kings County and Montefiore hospitals in the

morning and the Sea View, Bellevue and Kingston Avenue hospitals in the afternoon

Detailed information in regard to the program may be obtained from Dr. George Ornstein, 965 Fifth Avenue, New York City

BOOK REVIEW

Nomenclature and Criteria for Diagnosis of Diseases of the Heart The Criteria Committee of the New York Heart Association. Fourth edition. 282 pp. New York: New York Heart Association, 1939 \$2.00.

This book lists in detail the criteria for diagnosis of heart disease in all its aspects including the etiology, anatomical, physiological, radiological, electrocardiographic and pathological. It has been adopted and distributed by the American Heart Association and is recommended by the New England Heart Association whose predecessor the Boston Association for the Prevention and Relief of Heart Disease, pioneered in this field nearly twenty years ago.

The present volume contains important changes to conform with the *Standard Classified Nomenclature of Disease*, and a section on "Pathological Diagnosis" has been added.

The appearance of a fourth edition in twelve years is some indication of its popularity among cardiologists and teachers, who have welcomed the contribution it has made to clarity of expression through uniformity of criteria.

NUMBER 19

ACUTE APPENDICITIS AS A COMPLICATION OF CARCINOMA OF THE CECUM

MARSHALL K. BARTLETT, M.D.,* AND RICHARD H. MILLER, M.D.†

BOSTON

THAT obstruction of the lumen of the appendix may be the etiologic factor in acute appendicitis is a well recognized fact. In a recent study of 3400 cases of acute appendicitis, Collins¹ found such obstruction a causative factor in 50 per cent of the entire series.

A neoplasm of the cecum may obstruct the lumen of the appendix at the point where it enters the wall of the cecum and produce an acute inflammatory process in the appendix. In these cases the clinical picture of acute appendicitis obscures the underlying process, so that the presence of the neoplasm is usually not detected until some time later. This delay may allow the growth to become inoperable or incurable in the interval.

Two recent cases have drawn our attention to this condition, which is not a common one. We have succeeded in finding only 6 additional cases in the literature. In 4 of these the diagnosis of acute appendicitis was established at operation, while in the other 2 it was based on the clinical picture, which was considered conclusive. In all of them the diagnosis of carcinoma of the cecum was later proved.

Shears,² writing in 1906 reported the case of a woman of fifty-two who had two attacks of acute appendicitis, treated without operation. Later when laparotomy was performed a mass, which proved to be carcinoma, was found entirely surrounding the base of the appendix.

Nothing further on this subject is encountered in the literature until 1932, when Mayer³ described 2 cases. One was that of a woman of seventy who had an acutely inflamed but unruptured appendix, obstructed at its base by a carcinoma of the cecum. The other patient was a man of sixty-five with a gangrenous and perforated appendix who also had an underlying carcinoma of the cecum.

In 1933 Parker and Rosenthal⁴ reported a case of appendiceal abscess in a man of forty-four, who died of sepsis before a resection could be undertaken. He had a carcinoma of the cecum obstructing the orifice of the appendix.

Banks and Green,⁵ writing in 1935 reported the case of a man of sixty-three who had an appendiceal abscess which subsided under conservative treatment. A resection of the right colon was done, and an annular scirrhous carcinoma of the cecum surrounding the orifice of the appendix was found.

The latest article describing the coexistence of these two conditions is that of Cook.⁶ His patient was a woman of thirty-eight who had acute appendicitis with abscess, complicating an adenocarcinoma of the cecum.

In spite of its apparent rarity, we feel justified in again calling attention to this combination of conditions. In each of the cases that we are reporting a delay of several months occurred between the first operation and the recognition of the actual underlying disease. Even at the time of the final operation, a definite diagnosis of malignant neoplasm could not be made by the roentgenologist. As in other forms of cancer, the only hope of cure in this condition lies in its early recognition before the growth has become inoperable because of local extension, or the condition incurable because of metastasis.

There are two distinct factors that mitigate against the recognition of the presence of carcinoma of the cecum as an underlying process in acute appendicitis. One is that it is not considered good surgical judgment to explore adjacent organs in the presence of an acute inflammatory process, such as acute appendicitis. The other is that an underlying neoplasm may be mistaken for the varying degree of induration of the wall of the cecum that may be present in acute appendicitis.

*Assistant surgeon, Massachusetts General Hospital.

†Member Board of Consultation, Massachusetts General Hospital.

CASE REPORTS

CASE 1 The patient, a 32-year-old man, had been operated on 4 months before admission. The surgeon who operated stated that acute appendicitis was present and that the cecum was normal. The appendix was removed. After operation the patient had symptoms, including pain in the right lower quadrant of the abdomen, that were thought to be due to subacute intestinal obstruction, and 1 month after the appendectomy an exploratory laparotomy was done. A kinking of the terminal ileum was found and freed, and what was thought to be an acute inflammatory process involving the terminal ileum and cecum was noted. Because of the marked change in the cecum in 1 month, it was thought that the process was not tuberculous in origin, and a diagnosis of regional ileitis and colitis was made.

The patient continued to have pain in the right lower quadrant, and he was admitted to the hospital for study. An indefinite mass could be felt in the right lower abdo-

FIGURE 1 Case 1

This section of the tumor shows a rapidly growing and poorly differentiated growth, classed as adenocarcinoma, Grade IV. The patient was alive and well three years after operation.

men, and an x ray examination by barium enema revealed a mass in the cecum that was thought to be a benign neoplasm. Examination of the stool on two occasions showed no occult blood. At operation a polypoid adenocarcinoma was found, filling the cecum and lower ascending colon. No local extension outside the bowel had occurred, and no metastatic disease was felt. An ileotransverse colostomy was performed with removal of the terminal ileum, cecum, ascending colon and part of the transverse colon.

The patient made an uneventful convalescence and was living and well 3 years after operation.

CASE 2 The patient, a 52-year-old surgeon, had had diarrhea for several years. A diagnosis of mild colitis had been made. Four months previous to admission he had an acute attack of abdominal pain and a gangrenous appendix perforated at the base was removed. Some induration of the cecum around the base of the appendix was noted. The wound had drained for 4 weeks and then closed, and had remained closed. After this, mild attacks began, consisting of abdominal discomfort, gas and slight elevation of temperature. The diarrhea persisted.

On admission a small, firm mass could be felt under

the appendectomy scar. The temperature was 99°F., and the white-cell count 9700. X ray examination by barium enema revealed disease in the region of the cecum, but its nature could not be determined. Stool examination showed no occult blood.

At operation a hard, movable growth was found in the cecum. There were extensive metastases to the regional

FIGURE 2 Case 2

This section of the tumor shows a fairly differentiated growth, classed as adenocarcinoma, Grade III. Extensive metastases were found at the time of operation, and the patient died three months later.

lymph nodes, and the liver was studded with many carcinomatous nodules. A resection of the right colon with an ileocolostomy was done, and the patient had a satisfactory though somewhat stormy convalescence. The primary tumor was removed in this case in the hope of relieving the patient's symptoms for the remaining months of his life. He made an uneventful recovery from the operation but failed rapidly after leaving the hospital, and died 3 months after the operation.

SUMMARY

Carcinoma of the cecum may obstruct the lumen of the appendix and cause acute appendicitis.

A report of 2 cases is added to the 6 previously reported in the literature.

In the presence of a definite acute appendicitis the underlying carcinoma of the cecum may be overlooked.

A delay of four months occurred in each of our cases between the first and final operations.

Even at the time of the last operation, a definite diagnosis of carcinoma of the cecum could not be made in either case by the roentgenologist.

THE NATIONAL HEALTH ACT OF 1939*

ROBERT B. OSGOOD, M.D.†

BOSTON

I HAVE accepted the very kind invitation to take part in this symposium on the Wagner Health Bill with some reluctance. I believe that I am listed as a proponent of the bill, and it is true that I am in sympathy with its main purposes as I interpret them, but I am not a proponent of the bill as it now stands.

I should like to discuss the present situation under three headings: Causes for Worry, "Definition of the Issue" and "Attitude toward the Proposed Health Legislation."

CAUSES FOR WORRY

Several years ago Dr. Olin West¹ is said to have made a statement the substance of which is as follows: The outstanding problem of the medical profession is the delivery of adequate scientific medical service to all people, rich and poor, at a cost that can be reasonably met by them in their respective stations in life. I believe that this statement is as true today as it was when Dr. West made it. The problem has not been solved, and it behooves the medical profession to worry about it and to continue to seek its solution. In my opinion the evidence is clear that a real need for improvement in medical care exists.

The existence of this need was revealed by the findings of the Committee on the Costs of Medical Care² in 1932. It is well to remember that these studies were made during the boom years of 1928, 1929 and 1930, a fact which suggests that in the opinion of this committee the need then existed, and it would appear that the present depression has only intensified, not created, this need. It is not likely to be satisfied even if economic conditions improve.

The mass of more or less confidential and personal opinion assembled by the impartial American Foundation Studies in Government,³ and published in two volumes entitled *American Medicine*. *Expert testimony out of court* also proves the existence of an uneven distribution of medical care and of wide gaps in its adequacy.

I know of no reason to doubt the essential accuracy of the recent investigation of the Federal Government into the incomes of its citizens.⁴ If these figures are reliable there are some 40,000,000

persons living in families whose total annual income is below \$900. These people are not paupers, but among them will be numbered most of the so-called medically indigent. It is true that this sum may be able to buy twice as much in some localities as it will in others. Nevertheless \$900 a year in any section would seem to leave little margin either for budgeting or for buying the best that medicine knows as to prevention, diagnosis and treatment of illness or injury, if any of the members of an average family of four are in need. It seems quite unfair to load this uncompensated burden on the backs of wearied practitioners, and unwise to expect any longer a weakened public to shoulder it.

Another cause for worry is what one may call the increasing "consumer demand." The appetite of the lay public for information concerning medical matters has become voracious. This is evidenced by the books, written by both doctors and laymen, that are being published—and widely sold—and by countless articles in popular magazines and the daily press. The proposals for health legislation that are being introduced into Congress and the state legislatures are largely stimulated by this increasing consumer demand. The Health Conference in Washington in July 1938—at which the demonstration of the great need of improvement in medical care went unchallenged by organized and unorganized medicine,—made this demand much more audible. Physicians should neither underestimate the potential power of this demand nor fail to meet it with open minds, admitting that a genuine need exists and demonstrating their eagerness to satisfy it. I think that the recently published platform of the American Medical Association should help greatly in this respect.

Medicine is in the limelight. Physicians should court such illumination. If there are blemishes that need removal or portions of the structure that need alteration, physicians should be the first to suggest such changes because they are the experts who should plan them.

I wonder if this consumer demand can be met better by training a great chorus to sing "See how efficient we are! listen to what we have done!" than by admitting frankly the gaps in adequate medical care which for years have been known to exist,—and which the public has recently discovered,—and by demonstrating a readiness to at

*Read before the Medical Society of the County of New York, December 18, 1939.

†John B. and Burkhalter Brown Clinical Professor of Orthopaedic Surgery (emeritus) Harvard Medical School; consulting surgeon, Children Hospital, and member of consulting board Massachusetts General Hospital Boston.

tempt to close them. With a knowledge based on experience, and vastly more profound than the public can ever acquire, one should be able to overcome the effect of any false or evil-minded propaganda. One may even persuade well-meaning but less well-informed sociologists that physicians also have good intentions and are busying themselves about plans devised to achieve the ends that both doctors and welfare workers desire. Medicine, like the accused man at the bar, is surely entitled to be considered innocent until proved guilty, and so also are many of those who are proposing plans for the improvement of medical care. One should do well to remember the words of Sir Thomas Browne in his *Religio Medici*, "In all disputes so much as there is of passion, so much there is of nothing to the purpose, for then reason like a bad hound spends upon a false scent." If informed and fair-minded representatives of medical practice should sit around a council table with economists and sociologists and public-health officials, I believe that it would be both more dignified and more likely to realize the ends all physicians are seeking than it is to fight propaganda by propaganda and to throw down the gage of battle. It would certainly be less confusing and probably more profitable to the patients, who are the real consumers of medical care. Now that Dr. Goebbels has converted propaganda into a brutal science by sacrificing truth on the altar of expediency, I mistrust propaganda more than ever. I hope that medicine as well as this country may be kept out of war.

DEFINITION OF THE ISSUE

To define the issue one must start with a premise that is a definition of medicine's goal, the star to which the medical wagon must be hitched. Sir Arthur Newsholme,⁵ in *Medicine and the State*, sets the goal in the following thoughtful sentence, "In the first place, the health of every individual is a social concern and responsibility, and secondly, as following from this, medical care, in its widest sense, for every individual is an essential condition of maximum efficiency and happiness in a civilized community." In 1930, the British Medical Association⁶ also asked a question and answered it: "What kind of health service should be at the disposal of every member of the community? The answer is simple. Every kind of service which may be necessary for the prevention and cure of disease and for the promotion of full mental and physical efficiency." Dr. West's statement of what he considered to be the outstanding problem of medicine, to which I have referred, implies that in the solution of the problem the attainment of this same goal is sought.

The premise would seem to be that health is not a commodity and that every citizen and his or

her dependents have no more inalienable a right to "life, liberty and the pursuit of happiness" than to the protection, the maintenance and the improvement of their health by every means known to medicine, economics and sociology. One may take pride if one will in the fact that medicine in the United States has led the world in accomplishment and speed of development, nevertheless, this in no way frees physicians from eagerly striving to find the solution of Dr. West's problem, which has not yet been found.

It may help to clarify the issue if one recognizes the extent to which governments—local, state and federal—are already participating in medical care. Prophylaxis and treatment are no longer separated departments of medicine. They are inextricably bound together. In the British Medical Association proposals⁶ for a general medical service, published in April, 1930, under "Services Required," the first fundamental principle stressed is "that a satisfactory system of medical service must be directed to the prevention of disease no less than to the relief of individual sufferers." Under the caption of "For Treatment of Disease" appears this significant and I believe very sound statement, "In so far, however, as the individual doctor can promote the prevention of disease, this can be secured by associating every general practitioner with the general health service and emphasizing on every possible occasion the fact that there is no real line of demarcation between the preventive and curative branches of professional work." The proposals then point out the extremely important place that the family physician has always occupied and must continue to occupy in any satisfactory system of medical service.

The increasing dependence of practicing physicians on governmentally supported laboratories in this country is shown by the report⁷ of the Bureau of Social Hygiene of the Department of Public Health of the City of New York. The diagnostic services of this bureau are available to practicing physicians for the examination of their patients, for diagnostic and laboratory service and for consultation concerning diagnosis or treatment. Reports are made directly to physicians. The surprising increase in service rendered to physicians and the increasing use of the service made by them is shown, for example, in the examinations for syphilis. In 1934 there were 3411 examinations, in 1937 there were 5747 and in 1938 there were 8791, the latter is an increase of more than 3000 examinations in one year. There were over 29,000 more smears for gonorrhea and over 37,000 more blood examinations in 1938 than in 1937. The treatment services of this bureau are also being utilized by physicians to a larger and larger extent. These clinics are maintained for those unable to pay for either private care or voluntary

hospital care. Persons able to pay are referred to private physicians. In the four years 1934 to 1938 there was an increase in the total number of visits of over 370,000, and in the single year ending January 1, 1939, an increase of over 100,000.

According to the Report of the Committee on the Costs of Medical Care, there were in 1930 almost twice as many hospital beds in the United States supported by governments as by nongovernmental agencies. Private medicine, even helped by philanthropy, can no longer support our hospitals for mentally deranged patients. Many years ago there was much opposition from organized medicine to governmentally supported sanatoriums for tuberculosis. Few of us would oppose such support today. A consumer demand induced the Massachusetts legislature ten years ago to legislate the establishment of a special hospital for the investigation and treatment of cancer in the face of determined opposition from the State Department of Public Health and the medical profession. Recently the doctors—not the citizens—of the western part of Massachusetts have requested that another hospital for the same purpose be established in their community. The term "socialized medicine" is unpleasant to all physicians, but co-operation between local, state and federal governments and general practitioners surely represents a form of social service beneficial to both physicians and their patients.

ATTITUDE TOWARD PROPOSED LEGISLATION

I am still speaking only as an individual, but I am also utilizing material already assembled and printed by the Committee of Physicians for the Improvement of Medical Care, of which I am a member. Most of this material is taken from a printed statement issued by the committee and dated August 15, 1939, under the heading, "Proposals for Amendment of the Wagner Bill (S 1620)". In the bill as introduced by Senator Wagner its purposes are set forth in the following words, "To provide for the general welfare by enabling the states [I repeat, the states] to make more adequate provision for public health, prevention and control of disease, maternal and child health services, construction and maintenance of needed [I repeat, needed] hospital and health centers, care of the sick, disability insurance and training of personnel, to amend the Social Security Act, and for other purposes." There might possibly be some objection to amending the Social Security Act, and one must scrutinize the unnamed "other purposes" for which the bill has been drawn. Nevertheless, I think all physicians will agree that the main purposes as stated are

worthy and noncontroversial. The bill has received the general support of consumer groups—labor, farm and women's organizations and so forth—and has been subjected to both favorable and unfavorable criticism by various professional groups. The subcommittee of the Senate Committee on Education and Labor before which the hearings were held gave the impression of receptive open-mindedness and intelligent interest. The only hearing that I attended was conducted with dignity and complete fairness. I quote from the published report⁴ of this subcommittee at the conclusion of the preliminary hearings:

Federal legislation along the general lines followed by S 1620 based upon federal-state co-operative programs, is necessary to strengthen the health services of the nation and to make provision for the progressive and effective improvement of health conditions in all parts of the country and among all groups of people.

The role of the Federal Government should be primarily to give technical and financial aid to the states. The committee will continue to study S 1620 so that a definite report on the proposed legislation can be submitted soon after the beginning of the next session of Congress.

It would appear, therefore, that more of the matter will be forthcoming.

The Committee of Physicians for the Improvement of Medical Care has expressed its sympathy with the general purpose of the Wagner bill, and agrees with the American Medical Association that a functional co-ordination of all federal and medical activities is almost a necessity (Platform, American Medical Association, Statement No 1), that there should be an allotment of such funds as Congress may make available to any state in actual need for the prevention of disease, the promotion of health and the care of the sick, on proof of such need (Platform, American Medical Association, Statement No 2), and that there should be an extension of medical care for the indigent and medically indigent (Platform, American Medical Association, Statement No 5).

There would seem to be a fairly general medical consensus that if adequate medical care is to be made available to the people of this country, governments—local, state and federal—must assist in providing it, as indeed these governments are already doing. Experience has seemed to show that federal participation may best be effected by grants-in aid to the states on the basis of demonstrated need and of approved programs initiated by the states, administered by the states and, insofar as is possible, supported by the states.

The Wagner bill calls for large appropriations of federal funds. The national debt is increasing

and the budget is not yet balanced. As the Committee of Physicians⁸ has said

The provision of monies by the Federal Government to assist in medical care at once involves the government in the setting up of suitable machinery to see that the monies so appropriated are expended in such a way as not only to improve the medical care offered to the people but to maintain and improve the standards of the institutions and individuals participating in this care. Only by insistence upon this principle can the prudent use of public monies be guaranteed. Although provisions for this purpose are included in every title of the Wagner bill, there are certain features in these titles and in the bill as a whole that militate against the achievement of these objectives

The first of these is that divided control in the planning and execution of the program is incompatible with any sound program for national health, in other words there should be unified federal health authority. As a corollary to this there should be a federal general health council and local general health councils in the several states. The establishment of a unified federal health authority and of a general health council should be the first steps taken in connection with the institution of a national health program. Although special measures, such as those contained in Title V (Maternal and Child Health), Title VI (Public Health) and Title XII (Hospitals and Health Centers) of the Wagner bill may be expedient, the main objective should be to provide in every community a unified program of health service and medical care which will meet the standards approved by the health council that has been proposed. The committee believes that the lack of provision—in the bill as it now stands—for support of medical education and research may cut the ground from under good medical practice.⁸ The achievement and maintenance of the highest standards of medical education are the very foundation stones of high-quality medical practice. The committee considers this to be one of the most serious of the defects in the bill S 1620.⁹

In the draft of the Committee of Physicians to which I have referred there follow specific proposals including details concerning the method of appointment of the general federal health council and the character of its membership. It is stated "that representation of special interests should be subordinated to the more important point of assembling outstanding persons with imagination, intelligence, critical judgment and expert knowledge in public health and medicine, a majority of whom should hold degrees of Doctor of Medicine."⁸ The term of office should be sufficiently long to permit members of the council to look on membership in it as a career. These members should give full time to their duties, and remuneration

should be sufficient to attract persons of the highest quality. One will see that in such a set up an entirely experimental approach would be made to the federal treasury, and no appropriations would be asked for or made until need had been demonstrated and a program for meeting this need had been approved by the general health council. No grants-in-aid to the states would be made unless their programs and their estimated costs were approved by the general health council.

At the present moment only a very bold group of planners would feel itself able to state exactly how the health needs either of the different states or of the nation as a whole can best be met. It would be a still bolder group that in advance would be sure of being able to make any reliable estimate of the cost of meeting these needs, which is what the Wagner bill attempts to do. A system or various systems of improving medical care in the United States should be worked out in an evolutionary manner. The method of trial and error will often be necessary in order to enable one to determine the success or failure of any proposed system. However, physicians must do something about it, for undoubted need exists, and the consumer demand will be likely to become impatient if they delay in repeated attempts to make available all that medicine knows to larger and larger groups of citizens and their dependents. It is interesting to recall that in both the majority and minority reports of the Committee on the Costs of Medical Care,¹⁰ made seven years ago under the heading of "Co-ordination and Control of Medical Service," the importance of putting these measures into effect in the "immediate future" was stressed.

In closing I wish to say that I am in entire accord with the statement made by Dr Van Etten,¹¹ president-elect of the American Medical Association, in his Canandaigua speech of September 28, 1939, "It seems inevitable that the insurance principle shall be involved in plans for medical service, and it seems wise that many trials be made in the various states, such as are now proceeding in California and New Jersey, before national health plans shall be promoted." I subscribe to the belief, which I think is rather generally held, that no nationwide system of compulsory health insurance should be imposed, and that the non-profit voluntary systems which are spreading so fast should be given a fair and sympathetic trial.

Later in this same speech Dr Van Etten said

I believe that our people would be responsive to an American health program if the physicians of the country could be inspired to write it. I believe that it should strongly preserve the quality [I repeat, the

quality] of medical care, competently distributed. I believe that the units of health administration should be the states, and their political subdivisions where local needs are known. The general practitioner should be supported in his relationship to the American family

It seems hardly necessary for me to say that I am in accord with these statements also

The Committee of Physicians* has stated

To effect a real improvement in medical care, not only the distribution of medical care but also the quality of medical care must be continually improved. The intellectual equipment and technical proficiency required to understand and apply the new weapons that science has given us to combat disease have grown rapidly. The educational background that was adequate a decade ago is quite insufficient today. Knowledge becomes obsolete as rapidly as apparatus. Greater opportunity must be given not only for the initial training of physicians but for their continuous education. In fact the practicable level of quality in our medical services will ultimately depend upon our educational system. Investigations must also be fostered in order that our means for combating sickness and disability may be enhanced.

Society cannot afford to refuse financial support for measures that will curtail or eliminate disability. If it does refuse, it will be required to furnish larger sums for the continuing support of the results of this disability.

I have gained the impression that the interested lay public has been disturbed by what it thinks has been an inflexible attitude of certain medical and lay groups toward methods proposed for the improvement of medical care—an attitude which

the public interprets as standpoint. I am not one of those who believe that the individual physician has lost caste with the lay public or is in danger of losing caste. On the contrary, there seems to be evidence that the practicing physician is today treating his patients with more rather than less skill, and with as clear a conscience and as sympathetic an attitude as he ever exhibited in the horse-and-buggy age. As Sir Arthur Keith¹² once wrote concerning another medical advance, "Goodness knows we are a long way from finality." I fancy that physicians will still be a long way from finality for generations to come, for the star to which I have suggested the medical wagon should be hitched may be light years away 372 Marlborough Street.

PROGNOSTIC FACTORS IN CARCINOMA OF THE BREAST*

GRANTLEY W TAYLOR, M.D,† AND NORMAN H BRUCE, M.D ‡

BOSTON

IT IS a matter of common experience that a considerable number of cases of carcinoma of the breast, operable by the usual criteria and subjected to radical mastectomy, develop early recurrence of the disease, which runs a rapidly fatal course. In an effort to discover factors common to these cases and possibly of prognostic value, we have studied a group of 30 patients all of whom had received radical mastectomy, with subsequent rapid recurrence and death within eighteen months. For comparison, two other similarly treated groups were studied. One of these consisted of 48 patients who had died of recurrence after eighteen months, while the other was made up of 47 patients living and well five or more years after the radical mastectomy. These three groups will be designated throughout the discussion as "early deaths," "late deaths" and "cured cases." We are well aware of the fallacy of attempting to draw accurate statistical conclusions from groups of such small size. Many of the data are presented with the realization that nothing but gross impressions can be formed and only striking differences can be brought out. All cases in which radical operation was car-

aged forty-one, forty-five and fifty-nine, were all considerably better than the group average as regards operative risk. In the remainder of the group it will be seen that the typically bad risk patient was obese, old and hypertensive. Such an observation is in no way startling or unexpected, but cannot help but impress the surgeon with the danger of radical mastectomy for a patient of this type, particularly in view of the added technical difficulty that the obesity entails. In 6 cases the cause of death was pulmonary disease—4 patients dying from bronchopneumonia, and 1 each from massive pulmonary collapse and pulmonary embolus. In the remaining 6 cases the cause of death was sepsis originating in the operative wound, with subsequent systemic manifestations. In 4 of these, positive blood cultures were obtained, the streptococcus being the organism in each, and in 2 (Cases 6 and 11) infection developed after a Thiersch graft following an uneventful convalescence from mastectomy. In Case 6 intensive pre-operative radiation, as well as concomitant diabetes, without doubt contributed largely to the rapid septic course.

TABLE 1 Total Deaths in Patients Subjected to Radical Mastectomy

| TYPE OF DEATH | NO. OF DEATHS |
|-------------------------------------|---------------|
| Postoperative deaths | 12 |
| Deaths from recurrence within 18 mo | 30 |
| Deaths from recurrence after 18 mo | 48 |
| Deaths from intercurrent disease | 8 |
| Total | 98 |

ried out and in which death occurred later are listed in Table 1.

POSTOPERATIVE MORTALITY
